SUMMARY: In Europe almost 80 million tons of waste are annually combusted in Waste-to-Energy plants. Solid residues generated thereby contain altogether about 69,000 t/a of Zn, of which more than 50 % accumulates in air pollution control (APC) residues. Recent research activities aiming at Zn recovery from APC residues resulted in a large scale Zn recovery plant at a Swiss waste incinerator. By acidic leaching and subsequent electrolysis this technology (FLUREC) allows generating metallic Zn of purity >99.9%. In the present paper the economic viability of the FLUREC technology with respect to Zn recovery from different solid residues of waste incineration has been investigated and subsequently been classified according to the mineral resource classification scheme of McKelvey. The results of the analysis demonstrate that recovery costs are generally higher than the current market price of Zn, which implies that none of the identified Zn resources present in incineration residues can be economically extracted and thus cannot be classified as a reserve.

1. INTRODUCTION

In European Waste-to-Energy plants almost 80 million tons of waste are annunally combusted. Besides the production of electricity and heat, waste incineration goes along with the generation of bottom ash and Air-Pollution-Control (APC) residues, namely fly ashes (including boiler ash and filter ash) and filter cake. While in many countries bottom ash is already processed in order to recover some of the metals contained (mainly iron scrap, but also aluminium and copper), APC residues (which amount in total to about 2 million tons in Europe) have been hardly considered for resource recovery so far.

Only in few European countries attempts are made to recycle APC residues or at least parts of them. One of these attempts addressing metal recovery from fly ashes, recently resulted in a technical scale Zn recovery plant at a Swiss waste incinerator. By acidic leaching and subsequent electrolysis this technology (FLUREC) allows generating metallic Zn of purity >99.9%. In addition the FLUREC technology produces a concentrate containing high amounts of lead and copper, which can be sold to smelters.

Proceedings Sardinia 2015, Fifteenth International Waste Management and Landfill Symposium
S. Margherita di Pula, Cagliari, Italy; 5 – 9 October 2015

In the present paper the economic viability of the FLUREC technology with respect to Zn and also Pb and Cu recovery from different solid residues of waste incineration (bottom ash, boiler ash, and filter ash of different incineration and APC technologies) generated in the EU 28 + Switzerland and Norway has been investigated and subsequently been categorised according to the mineral resource classification scheme of McKelvey (see Figure 1).

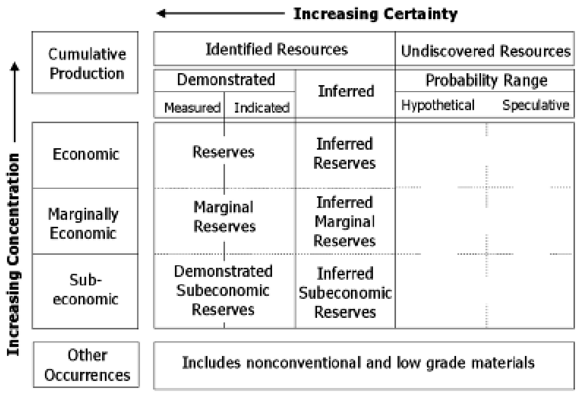

Figure 1. McKelvey diagram illustrating resource reserve terminology (after McKelvey, 1972)

2. MATERIAL AND METHODS

In general, the procedure illustrated in Figure 1 has been followed. Due to the fact that investigations have a priori been dedicated to the waste incineration residues, the first step of resource prospection has been left out in the frame of the present investigations.

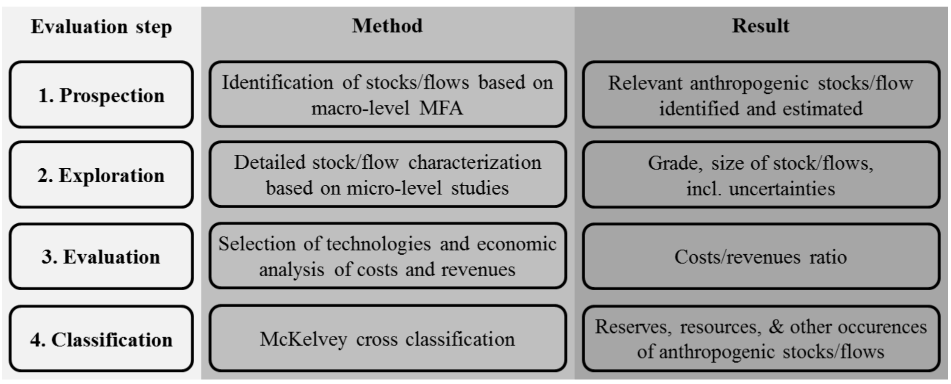

Figure 1. Procedure for the evaluation of anthropogenic resources (Lederer et al., 2014)

2.1. Exploration of Zn flows in MSWI residues

In order to explore residues from waste incineration as potential secondary resource for Zn a detailed literature analysis focusing on the following issue has been conducted:

- quanitites of waste utilized in European WTE plants(CEWEP, 2011)(CEWEP, 2011),
- incineration technology applied at European WTE plants - distinguishing between grate incineration & rotary kilns and fluidized bed incineration (ISWA, 2006, 2013),

- air pollution control APC systems (wet, dry & semi-dry residue systems) used at European WTE plants and the respective amount of APC residues generated (ISWA, 2006, 2013), and
- Zn content in different MSWI residues (Abe et al., 2000; Aubert et al., 2007; Aubert et al., 2004a, b; Auer et al., 1995; Boesch et al., 2014; Bontempi et al., 2010; Chiang et al., 2008; De Boom et al., 2011; Fedje et al., 2010; Ferreira et al., 2005; Hallgren and Strömberg, 2004; Hjelmar, 1996; Jakob et al., 1996; Karlfeldt Fedje et al., 2010; Karlsson et al., 2010; Lam et al., 2010; Mangialardi, 2003; Nagib and Inoue, 2000; Nowak et al., 2013; Quina et al., 2008; Schlumberger, 2010; Van Gerven et al., 2007)

Based on the results of the literature survey a detailed material flow MFA model describing the flows of Zn through European WTE plants has been established.

2.2. Economic Evaluation of Zn flows

The MFA model together with detailed information about the Zinc recovery technology FLUREC (amount of consumables, electricity consumption, etc.) forms the basis for the economic evaluation of Zinc recovery from incineration residues.

Figure 2 gives an overview of the FLUREC technology and summarizes the required operating supplies. Detailed information about the specific quantities of the latter together with data about products and by-products are of major importance for the economic evaluation and haven been published by Boesch et al. (2014) who performed a LCA on waste incineration enhanced with new technologies for metal recovery.

These data about energy and material flows were subsequently linked with market prices for the different operating supplies p_{OP_i} (including electricity) and for the final product, which is Zinc metal of purity > 99.9%, p_{Zn}, as well as specific costs c_{DP_i} for landfilling residues generated and necessary investment costs of the technology C_{INV} (see Equation 1). The overall costs of the FLUREC technology C_{Flurec} were then compared to the costs of the prevailing management practice of MSWI fly ash in Europe C_{CP} (Equation 2), which includes cement stabilization with subsequent disposal at non-hazardous waste landfills or direct landfilling at hazardous waste sites. Merging Equation 1 and 2 by assuming that the overall costs for the FLUREC technology should be not lager than costs for the current practice of fly ash disposal, specific production costs for secondary Zn c_{Zn} [€/kg Zinc] can be determined (see Equation 3). In case that specific production costs c_{Zn} are lower than the market price p_{Zn} for metallic Zn, recovery of Zn (using the FLUREC technology) is economically viable and vice versa.

In order to account for the fact that all data required for the economic evaluation (physical mass flows, prices, costs for disposal of residues or investment costs) are uncertain, plausible data ranges were defined and subsequently used to perform Monte Carlo simulations. For the definition of the uncertainties ranges temporal (i.e. over the last 5 years) and spatial variations in market prices and costs for disposal have been considered. The uncertainty of specific materials flows and energy consumption of the FLUREC technology has been estimated based on information provided by Schlumberger (2006) and Boesch et al. (2014).

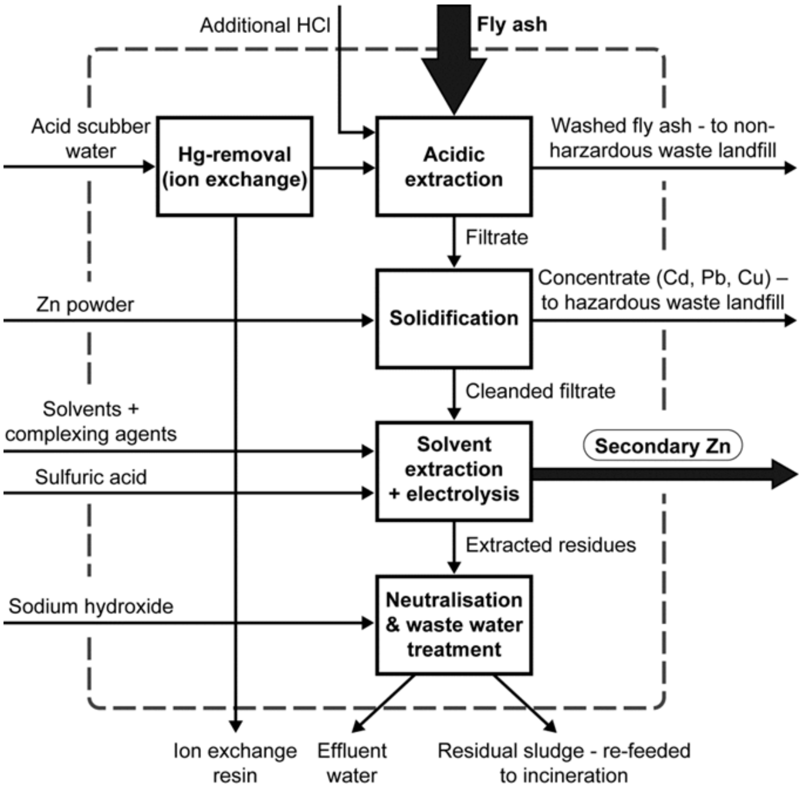

Figure 2. Schematic process diagram of the FLUREC technology (acidic fly ash leaching with integrated zinc recovery – Fellner et al., 2015)

$$\sum_{i=1}^{n} m_{OP_i} \cdot p_{OP_i} + \sum_{j=1}^{m} m_{DP_j} \cdot c_{DP_j} - m_{Zn} \cdot p_{Zn} + C_{INV} = C_{FLUREC} \qquad \text{Equation 1}$$

$$\sum_{j=1}^{m} m_{DP_j} \cdot c_{DP_j} = C_{CP} \qquad \text{Equation 2}$$

$$c_{Zn} = \frac{\sum_{i=1}^{n} m_{OP_i} \cdot p_{OP_i} + \sum_{j=1}^{m} m_{DP_j} \cdot c_{DP_j} + C_{FLUREC} - C_{CP}}{m_{Zn}} \qquad \text{Equation 3}$$

m_{OP_i} ·	specific mass of operating supply i [kg/t fly ash] and specific energy demand [kWh/t fly ash]
m_{DP_i}	specific mass of residue j to be disposed of [kg/t fly ash]
m_{Zn}	specific mass of metallic Zn recovered [kg Zn/t fly ash]
p_{OP_i}	market price for operating supply i and energy demand [€/kg] or [€/kWh]
p_{Zn}	market price for metallic Zn [€/kg]
c_{Zn}	production costs for metallic Zn [€/kg]
c_{DP_j}	specific costs for the disposal of residue j [€/kg]
c_{FLUREC}	specific overall costs for the FLUREC technology [€/t fly ash]
c_{CP}	specific overall costs for the current disposal management of fly ashes [€/t fly ash]
c_{INV}	specific investment costs for the FLUREC technology [€/t fly ash]

2.3. Classification of Zn flows

The classification of Zn present in waste incineration residues has been accomplished in accordance with (Lederer et al. 2014) who based their evaluation framework for anthropogenic resource on McKelvey (1972). The approach considers both, the economic viability of extracting a secondary raw material from a resource and producing a tradable good, and the knowledge of the existence of the resource. For the economic classification, McKelvey suggests the following terms. Resources are *economic* or *recoverable* if they can be extracted with a profit. Therefore, the production costs must be below the market price of the product achievable, which means in our case $c_{Zn} < p_{Zn}$. Resources for which the production costs are higher than the price, but not by more than a factor of 1.5, are *marginally economic*. Resources above this value are termed as *submarginal* or *subeconomic,* whereby according to Lederer et al. (2014) a threshold factor of 10 times the market price is assumed ($p_{Zn} < c_{Zn} < 10 \times p_{Zn}$). Resource flows whose production costs are above the threshold (of 10 times the market price) are counted as *other occurrences,* as for these materials no future prospection for econocmic recovery exists.

The classification according to the certainty of the existence of a resource flow/stock is structured as *identified – demonstrated*, *identified – inferred*, and *potentially undiscovered*. To perform this classification, the uncertainties determined for each Zn flow in the residues of MSWI are used. *Identified – demonstrated* resources are of proven existence and knowledge is highly certain (confidence that the actual flow of Zn is at least this size is 90%). *Identified – inferred resources* are defined here as the amount of Zn flows between the lower uncertainty bound (confidence 90%) and the mean value of the flow). The same amount of the material (due to symmetric uncertainty ranges) is designated as *potentially undiscovered* resources, which may exist but are highly uncertain. Finally, a cross-classification is accomplished considering both, economic viability and knowledge. Therein, reserves are resources that are both identified – demonstrated and economically extractable.

3. RESULTS

3.1. Exploration of Zn flows in MSWI residues

About 78 million tons of waste have been utilized in European (EU-28 + Norway and Switzerland) WTE plants in 2011. This equals to about 90% of the total waste incineration capacity (about 86 million tons) installed. Out of the 78 million tons 4.2 million tons are combusted in fluidized bed incinerators (FBI), the remaining part is utilized in rotary furnaces or grate incinerators (GI). According to information (data of 350 plants out of 470 plants in total have been available) provided by ISWA (2006, 2013), about 45% of the incineration plants are equipped with wet flue gas cleaning systems, 29% with semidry and 26% with dry systems. The discrimination of the incineration technology (grate vs. fluidized bed) and APC system (wet-semidry-dry) is of significant importance for the exploration of Zn flows, since the technologies do not only strongly influence the size and grade (with respect to Zn content) of fly ashes (see Table 1), but also the need of operating supplies (e.g. consumption of HCl) as well as costs for the current disposal practice. Fly ashes from FBI, for instance, are likely to be disposed of at non-hazardous waste landfills (due to their comparatively lower contents of heavy metals and salts), whereas fly ashes from grate incinerators (GI) are definitely classified as hazardous and have therefore to be disposed of at hazardous waste landfills. In Table 1 main outcomes of exploring waste incineration residues as potential resource for Zn recovery are summarized. Based on the analysis of data from numerous WTE plants, it becomes obvious that both, the APC system installed and also the type of fly ash (filter ash vs. boiler ash), strongly influences the Zn content of the fly ash. Whereas for dry or semidry APC systems average Zn contents of fly ashes amount to about 11,000 mg Zn/kg, wet systems may generate residues with Zn contents of about 20,000 mg Zn/kg fly ash (in case boiler and filter ash are collected together) or even above 40,000 mg Zn/kg fly ash (in case that filter ash is withdrawn separately).

Table 1. Analysis of fly ash amounts (kg fly ash/t waste) generated at Waste-to-Energy (WtE) plants with different APC systems and their respective Zn contents (mg Zn/kg fly ash) – after Fellner et al. (2015)

	Amount of fly ash [kg/t waste input]			**Zn-content in flue gas cleaning residues** [mg Zn/kg fly ash]			
	Flue gas cleaning system			Boiler and filter ash of			filter ash of wet systems*
	Wet	semidry	dry	wet systems	semidry systems	dry systems	
mean	24	40	38	**21,600**	**11,300**	**12,000**	**41,300**
median	25	39	39	17,300	10,300	10,800	42,900
10% quantile	16	33	27	12,400	7,300	7,600	20,200
90% quantile	30	49	48	35,800	15,500	18,500	60,300

* plants with separate collection of filter ash and boiler ash

Based on transfer coefficients describing the portioning of Zn during waste incineration (between 50% and 60% of Zn is transferred to the fly ash) and the data given in Table 1 the average content of Zn in the waste feed of European WtE plants have been determined to about 900±150 mg Zn/kg waste. Considering this content and the overall mass of waste combusted the following material flows have been derived: In total about 69±9 kt of Zn are annually fed into European waste incineration plants. Almost half of it (32.5±3 kt) accumulates in residues (bottom ashes and fly ashes of fluidized bed incinerators) at average concentrations below 6,000 mg Zn/kg ash. About 17±2.5 kt of Zn are present in boiler and filter ash of grate incinerators equipped with wet APC systems (average Zn content about 21,000 mg Zn/kg ash) and almost the same amount (18.5±2 kt) can be found in fly ashes from dry and semidry APC systems (average Zn content of 11,000 mg Zn/kg ash).

3.2. Economic evaluation and classification of Zn flows

Based on the material and energy demand of the FLUREC technology and the potential recovery rates for Zn (provided by Boesch et al., 2014) the different MSWI residues have been evaluated regarding their specific costs for Zn recovery. In Table 2 all assumptions made for the economic evaluation of Zn recovery from filter ashes of wet APC systems are summarized. The results indicate that despite the comparatively high Zn contents (around 41,000 mg Zn/kg ash) of those ashes, the specific production costs for Zn are about 1.8±0.8 €/kg Zn and thus, slightly above the current market price of 1.6 €/kg Zn (average price during the last 5 years). For the other fly and bottom ashes of European waste incinerators, specific production or recovery costs of Zn are even much higher (see Figure 3).

Table 2. Economic evaluation of Zn recovery from MSWI residues (using the example of filter ash from wet APC systems) applying the FLUREC technology (Fellner et al., 2015)

	Means of production & outputs	**Materials and energy** (per 1 t of fly ash)			**Specific costs (positive) & spec. benefits-savings (negative)**			**Total costs/savings**
		unit	**mean**	**standard deviation**	***unit***	**mean**	**standard deviation**	**mean**

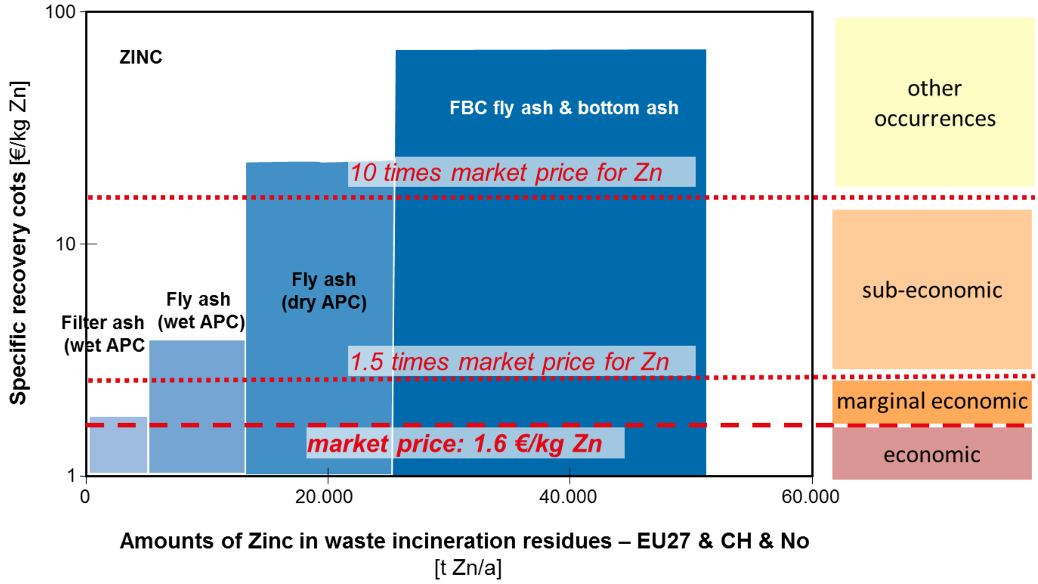

Figure 3. Specific production costs for Zinc (given in €/kg Zn) for different MSWI residues and their respective amounts of Zinc

Combining information about the size of Zn flows (incl. their uncertainties) and the specific recovery costs allows classifying Zn flows in accordance to classification scheme for mineral resource (Mc Kelvey, 1972). The results of this classification (see Table 3) demonstrate that total size of the identified Zn flows in European MSWI residues is 69,000 t/a. Based on the current market prices for Zn (1.6 €/kg), none of the identified resources can be economically extracted and thus cannot be classified as a reserve. The reserve base containing marginally economic and identified – demonstrated resources amounts to 4,100 t (separately collected filter ash from wet APC systems). A total of 6,800 t of Zn is classified as subeconomic, with production costs approximately 2.5 times above the current market price of Zn (boiler ash and jointly collected boiler and filter ash from wet APC systems). The residual majority of Zn is either low-grade fly ash from dry or semidry APC systems (10,400 t of Zn), from bottom ash (21,200 t) or from fly ash generated at fluidized bed incinerators (1,300 t).

Table 3. McKelvey diagram for annual Zn flows (in t/a) in European MSWI residues (the uncertainty ranges of the estimates form the basis for the distinction between *demonstrated*, *inferred*).

	identified resources		potentially undiscovered resources
	demonstrated	inferred	
economic	0[a]	0[a]	0[a]
marginally economic	4,100[b]	700[b]	700[b]
subeconomic	6,800[b]	1,100[b]	1,100[b]
other occurrences (low grade) low-grade materials	47,400	7,900	7,900
total	69,000		

a an economically viable recovery of Zn from fly ashes would (at current market prices) only be possible at Zn contents above 55,000 mg/kg ash

b assuming that at 50% of all WtE plants with wet APC systems filter ashes can be separately collected from the boiler ash

In comparison to total European Zn imports, which amount to about 1.3 million tons (Spatari et al., 2003), Zn recovery from *marginally economic* and *subeconomic* MSWI residues could at maximum substitute 0.8% of European imports.

AKNOWLEDGEMENTS

The authors would like to acknoldge the funding of the present study which was provided by the Austrian Federal Ministry of Agriculture, Forestry, Environment and Water Management. In addition we thank the operators of the Waste-to-Energy plants for their cooperation.
