Second harmonic generation

A B S T R A C T

A systematic study on the thiophene ring-fragmentation (TRF) reaction, yielding the Z-isomer of ene-yne type compounds, is presented. The investigations focus on the origins and pathways of potential side-reactions, resulting in an advanced synthetic protocol featuring enhanced selectivity and efficiency. The fragmentation threshold temperatures as well as reaction kinetics have been investigated utilizing inline infrared spectroscopy revealing unexpected results particularly concerning the reaction order (zero-order process). With regard to safety, selectivity, and up-scaling a flow-chemistry procedure for the TRF reaction has been developed. Finally, the technological relevance of the ene-yne structural motif is extended by a new design concept for NLO-chromophores showing the highest second harmonic generation efficiencies reported for these scaffolds.

1. Introduction

The base induced ring-opening reaction of heterocycles is a well-established methodology in organic chemistry.1 In particular, the organo-metal intermediated ring-fragmentation of thiophene derivatives, leading to “ene-yne” type compounds, is one of the best-studied ring-opening reactions.1–3 Early observations of the formation of “unsaturated aliphatic products” from 3-thienyllithium date back to 1962,4 however, the mechanism has not been understood at that time. The first report on controlled ring-fragmentation was given by Gronowitz et al. in 1969 on the sele-nophene structure.5 These findings were followed by publications of S. Gronowitz et al.6 and K. Jakobsen7 demonstrating thiophene ring-opening reactions; similar studies on benzo[b]thiophene were presented by B. Iddon et al.8 Recent extensions of the strategy represent double-sided ring-opened species via a tandem fragment-ation process.9–11

Thiophene ring-fragmentations (TRF) (Scheme 1) proceed with remarkable stereoselectivity yielding Z-isomers, selectively1–3,5–11, alternative approaches to synthesize these scaffolds typically suffer from poor regio- or/and stereoselectivity.1 Driven by the broad variety of potential applications, intense research in the development of stereoselective approaches via e.g. carbo- or hydro-thiolation, in order to obtain Z-organylthioenynes but also vinyl sulfides12–17 has been reported.

The scope of possible modifications, functionalizations (e.g. cycloaddition, Sonogashira-coupling, Michael-addition, nucleophilic substitution, oxidation) and applications of TRF-products was demonstrated to be widespread.18 Another important factor for applications, e.g. in materials science, is the potential to selectively oxidize the alkylthio group.18,19 This strategy enables to convert the –M- (alkythio) directly into a –M-substituent (sulfoxide or sulfone), thus significantly influencing electronic properties.20

Moreover, ene-yne substructures are found in natural products (e.g. Anthemis species)21–23 and, thus, represent attractive building blocks for total synthesis. Organylthioenynes are also useful syn-thons in organic synthesis, as these scaffolds can be utilized as precursors to enediyynes and other functionalized olefins.18 Vinyl sulfides are widely applied in organic synthesis as versatile inter-mediates14 and were identified in several biologically active...
molecules. In particular, aromatic vinyl-sulfide derivatives are found in various pharmaceutically active drugs against important diseases such as Alzheimer’s, Parkinson’s, diabetes, AIDS, and cancer. For potential pharmaceutical applications the selectivity of the synthetic approach with respect to double bond geometry is an important issue.

Recently, our group has reported on ene-yne derived nonlinear optical (NLO) materials capable of second harmonic (SH) generation. Direct functionalization of TRF-products via copper(I)-catalyzed azide-alkyne cycloaddition (CuAAC) applying phenylazide yielded NLO materials featuring twice the SH-generation efficiency due to an increased electron density leading to enhanced hyperpolarizability.

Applications in the field of materials science in particular necessitate efficient and reliable synthetic access to TRF-products. Here, we present a systematic study on the thiophene ring-opening approach focusing on origins and pathways of potential side reactions. As a result, an advanced procedure leading to opening approach focusing on origins and pathways of potential side reactions is given in chapter 2 in the Supplementary Data (acid-induced isomerization pathways).

2. Results and discussion

2.1. Thiophene ring-fragmentation

In the course of our research on NLO materials, utilizing (Z)-trimethyl(4-(methylthio)pent-3-en-1-yl)silane (3a, Scheme 2) as an ene-yne scaffold, deviations from the synthetic protocol (e.g. loss of inert atmosphere) resulted in an unexpected E/Z-isomerization of 3a toward the E-species 3f (typically in the range of 1–5%). For this reason, the impact of the reaction components on the isomerization was evaluated. It could be shown that neither the used dry solvent (Et2O), the reactants (2a, n-ButI, Mel) nor the organic by-products (n-ButBr) are associated with this process. However, the addition of LiI, which is formed during quenching of the TRF reaction using MeI, results in an isomerization of 3a. By evaluating various salts containing Li⁺ or I⁻ ions (LiCl, LiBr, LiClO₄, LiI, NaI, KI and TBAI – see Supplementary Data) it was established that the iodide anion is responsible for this side-reaction. Interestingly, this reaction showed enhanced rates in the presence of oxygen; argon atmosphere significantly limits this effect.

From these experiments we concluded that the formation of elemental iodine (I₂), even if only present in traces, is the origin of the formation of the E-species. This I₂-induced process of double bond isomerization is well-described in literature. Indeed, a control experiment revealed that the addition of I₂ (1 mol%) induces this reaction (Fig. 1); full exclusion of light suppresses the isomerization.

To further quantify this side reaction, 3a and the corresponding E-isomer 3f were subjected to UV-light assisted isomerization experiments. The reactions were carried out in standard NMR tubes using an I₂ solution in CDCl₃ at concentrations of 1.0 mol% and a standard light source. The results for 1.0 mol% I₂ are illustrated in Fig. 1. The experiment yielded the same E/Z-ratio starting from both, the pure Z- and E-isomer, indicating that complete equilibration is reached during the I₂-induced isomerization. Additional experiments using 10.0 mol% I₂ and starting material 3a revealed that an equilibrium state between the Z- and E-isomer is already reached within 15 s of light irradiation.

The equilibrium state consists of 16% 3a (Z-isomer) compared to an 84% 3f (E-isomer), corresponding to the thermodynamic energy level difference between the Z- and the E-isomer as indicated by DFT calculations. This fact clearly points out the importance of the TRF approach to obtain the thermodynamically less favored isomer. Moreover, the strategy potentially allows obtaining the corresponding E-structure in good yields. Indeed, repeating this experiment on preparative scale (using a 1.0 mol% I₂ solution) resulted in 76% of pure (E)-trimethyl(4-(methylthio)pent-3-en-1-yl)silane (3f) after column chromatography.

Hence, various alternative methylation sources were assessed. These experiments revealed that iodomethane (MeI) clearly outperforms the applied analogs (trifluoromethanesulfonate (MeOTf), dimethyl sulfate (Me₂SO₄) and methyl 4-methylbenzenesulfonate (MeSO₄)) with regard to efficiency and selectivity. Further information on potential side reactions is given in chapter 2 in the Supplementary Data (acid-induced isomerization pathways).

As a consequence, the second approach was to avoid the formation of I₂. On the one hand, the removal of I⁻ with Ag⁺-salts (e.g. Ag₂CO₃) and, on the other hand, the addition of a reducing agent were attempted for this purpose. In both cases, the formation of E-isomer was entirely suppressed. Particularly the application of Na₂SO₃ as the reducing agent prior to the addition of MeI proved to be advantageous. This new procedure for TRF, also applying slightly modified reaction parameters, combines both the prevention of the isomerization and the ease of workup. In addition to the significant improvement in stereospecificity an enhanced isolated yield of 86% (vs. 76–81% using the old procedure) for 3a was obtained, which shows the efficiency of the protocol.

To demonstrate the scope of the developed protocol, various substrates for TRF reactions were evaluated (Scheme 2). The modifications of 2a include the introduction of more stable silyl groups R (from TMS to TBDMS and TIPS) and variation in the substituent R in the thiophene 5-position (from sp² to sp³ and sp hybridization). The diversity of suitable silyl groups is an important factor with regard to specific functionalization. The alteration towards sp³ and sp centers for R derives from the current interest in these compounds as organic functional π-systems (e.g. NLO materials).

Detailed synthetic protocols for the synthesis of precursors 2a-e via Halogen-Dance reactions and TRF towards 3a-e are given in the experimental section. Applying the novel TRF protocol all ring-opening reactions were accomplished successfully and in good yields of 75–86% without any formation of E-isomer; the proof for the formation of the Z-isomers has been given by X-ray diffraction.
on various examples.\textsuperscript{37,38} A tendency towards lower yields for larger silyl groups (3a/3b/3c = 86%/82%/75%) and an increase in yields for sp to sp\textsuperscript{2} and sp\textsuperscript{3} hybridization of R' (3e/3d/3a = 77%/81%/86%) has been observed (see Table 1).

2.2. Kinetic investigations

Although the TRF reaction has been extensively studied regarding the substrate scope, no kinetic data is available. Based on previous investigations\textsuperscript{26} on organo-lithium compounds an ATR-IR probe was applied for inline reaction monitoring to explore the ring-opening process under dynamic conditions in order to gain insight on fragmentation threshold temperatures and reaction kinetics. Recent progress in the development of mid-IR transparent fibres\textsuperscript{40} and sensor assembly render it possible to achieve reliable data even under non-isothermal conditions. This allows for a monitoring of the TRF reaction in a warm-up phase yielding the onset temperature of the ring-opening. The inline approach (both in situ and real-time) is of critical importance for this study, since alternative techniques typically suffer from sample alteration during sampling.\textsuperscript{39}

In the initial experiments the fragmentation threshold temperatures were matter of interest. For this purpose the respective substrates (2a, 2b, 2d, 2e) were lithiated via metal-halogen exchange using n-BuLi (1.1 eq.) at −60 °C in anhydrous Et\textsubscript{2}O (0.2 M). The fragmentation of the TIPS-substituted derivative 2c could not be monitored under the applied conditions due to the low solubility in Et\textsubscript{2}O at −60 °C. After completion of the lithiation process the temperature was raised to ~0 °C at a constant rate (0.5 °C/min). Indeed, the formation of intense new absorption bands, particularly in the fingerprint region (650–900 cm\textsuperscript{-1}), were reproducibly observed for all substrates at certain temperatures. These bands reveal a significant correlation to peaks located between 2100 and 2200 cm\textsuperscript{-1} (highly specific for C–C triple bonds), which confirms the onset of the TRF reaction forming the ene-yne moiety. However, due to the self-absorption of the applied ATR-unit these bands were not utilized for quantitative analyses. The obtained concentration profiles during the ring-opening of 2a are exemplarily depicted in Fig. 2 (profiles for all fragmentation products are given in the Supplementary Data). Remarkably, the obtained ring-opening temperatures (defined by a 5% intensity threshold relative to the baseline) are in contrast to literature values. Whereas thiophene ring-fragmentations are typically reported to occur at room-temperature,\textsuperscript{1,2} we observed reaction onset temperatures of −50 °C, −47 °C and −42 °C for 2a, 2b and 2e, respectively. Only the fragmentation of 2d was found to take place at higher temperature (−24 °C), which is attributed to stabilizing effects of the phenyl substituent (see Table 1).

Furthermore, we investigated the TRF of 2a under isothermal conditions (−45 °C, −40 °C and −35 °C). A linear time dependence was observed for the product formation at all temperatures (Fig. 3) indicating a zero-order reaction, typically found for saturated catalytic processes. The reaction rates plotted against 1/T also show the linear dependence required by the Arrhenius equation, confirming this assumption (Supplementary Data). This finding is in obvious disagreement with the reaction mechanism depicted in Scheme 1, which implies a first-order reaction. To gain further insights we applied an excess n-BuLi and altered the concentration (0.13 M) of 2a, however, did not find any significant influence of the variations on the reaction rate. At this point, the reason for the zero-
order kinetics is not understood and remains to be clarified by future research.

2.3. Flow chemistry

Problems associated with solvent interactions, highly exothermic reactions and other safety issues limit the applicability of organolithium reagents to low temperature regimes. Unfortunately, the scale-up of cryogenic reactions employing hazardous organolithium reagents to low temperature regimes. Unfortu-

exothermic reactions and other safety issues limit the applicability of such a microflow reactor guaran-
tees fully inert atmosphere which is of crucial importance in order to avoid the formation of the undesired E-isomer. Low fragmenta-
tion temperatures observed during IR-experiments allow for short residence times in a microflow reactor under convenient tempera-
ture (Fig. 4).

A stainless steel microreactor was fabricated (Fig. 5), consisting of individual pre-cooling zones for reagents (200 μL volume each), T-shaped mixers and two microfluidic reaction zones – one for the lithiation (1 mL volume) and one for the quench (1.5 mL volume). In order to allow reaction temperatures down to −40 °C, a dual-stage Peltier-assisted cooling module was developed (FlowChiller), and attached to the bottom of the stainless steel reactor.

Precooled solutions of 2a (1.0 eq., 0.1 mol L$^{-1}$ in Et$_2$O) and n-ButLi (1.1 eq., 1.6 mol L$^{-1}$ in hexanes) were mixed and lithiation as well as TRF was accomplished in the lithiation reactor. Subsequently, a solution of Mel (1.8 eq., 0.35 mol L$^{-1}$ in Et$_2$O) was added and methylation of the thiolate took place in the quench-reactor. Finally, after leaving the microflow reactor, the reaction mixture was collected in a vial containing a Na$_2$SO$_3$ solution to avoid isomerization induced by atmospheric oxygen. Reaction tempera-
ture (−40 °C, −20 °C, 0 °C and room temperature) as well as $t_R$ (5–60 s) in the lithiation reactor were varied in order to identify ideal reaction conditions. Overall recovery of product, starting material and dehalogenated starting materials was approximately 75–80% at room temperature and almost quantitative beneath −20 °C. While virtually no product formation was observed at −40 °C (as expected from kinetic data), low conversion (34% yield) towards 3a took place at $t_R$ = 60 s at −20 °C. Notably, in both experiments only small amounts of dehalogenated by-product were formed, while the majority of the recovered material was starting compound 2a indicating that TRF proceeded rapidly compared to the initial lithiation in the investigated temperature regime. At 0 °C significantly increased product formation was observed for higher values of $t_R$, while best results were obtained at room temperature (Fig. 6). Fragmentation is basically completed after 20 s and the highest yield (73%) was found at $t_R$ = 30 s. Remarkably, no formation of the E-isomer was observed in any of our experiments. Variation of $t_R$ in the quench-reactor did not significantly influence the outcome of the experiment. More detailed results of the screening are given in Table S2 and S3 in the Supplementary Data.

Applying the optimized conditions, a run on a preparative scale (12 mmol, room temperature, $t_R$ = 60 s) was conducted. After pu-
fication by column chromatography, 3a could be obtained in 56% yield.

2.4. Non linear optical properties

Recently, we showed that replacing sulfur by selenium in ene-
yne derived NLO-materials significantly boosts the SH-efficiency. This outcome can be attributed to increased density of delo-
calized electrons in the conjugated π-system and thus enhanced hyperpolarizibility. However, the application of selenium is accompanied by drawbacks such as the toxicity of organo-selenium compounds and complex synthesis of the required precursors. We therefore adopted a novel design strategy to increase the electron-
density in the conjugated π-system. By attaching electron-donating substituents to the phenyl subunit, the molecular architecture was extended to a donor-acceptor-donor structure as depicted in Scheme 3.

The syntheses of 5i-iii were accomplished via CuAAC starting from 3a and the corresponding azides 4i-iii in moderate to good yields (5i: 82%, 5ii: 34%, 5iii: 57%). A fundamental prerequisite for SHG (second harmonic generation) is the crystallization in a non-
centrosymmetric crystal class, with the exception of 432. Unfortunately, 5ii$^{45}$ and 5iii$^{46}$ both crystallized in the centrosymmetric space group $P2_1/c$. In contrast, enantiomorphic crystals of 4i$^{44}$ (space group $P2_1$), Flack parameter 0.00(2) were grown by slow solvent evaporation (EtOH) > 25 °C. A second centrosymmetric polymorph of 4i$^{47}$ (space group: $P2_1$) was obtained by growing crystals from a saturated EtOH solution upon cooling to ~ 5 °C.

The molecules in the $P2_1$ polymorph of 5i (Z = 1) crystallize in layers parallel to (001), whereby the molecules are significantly
inclined with respect to the stacking direction (Fig. 7). Inside these layers, molecules related by translation along \(a\) are connected via face-to-face contacts of benzene to triazole rings (distance of least squares planes defined by the benzene rings of two adjacent molecules 3.519 Å).

The \(P2_1/c\) polymorph \((Z' = 1)\) is crystallo-chemically unrelated to the \(P2_1\) polymorph. The conformations of the molecules in both polymorphs differ regarding the orientation of the methoxy group and the molecule in the \(P2_1\) polymorph is considerably more twisted: The least squares planes defined by the non-H atoms of the benzene ring and the triazole ring form an angle of 26.7°, while the benzene and CH-\(\text{CS-CH}_3\)-fragment form an angle of 18.9°. The analogous angles in the \(P2_1/c\) polymorph are 9.0° and 8.7°.

Enantiomorphic crystals of \(5\text{i}\) were subjected to SHG measurements (Fig. 8). Compared to parent compound \(1\) (Scheme 3; \(R = \text{H}\)) \(5\text{i}\) \((R = \text{OMe})\) exhibits 35-fold increased SHG-efficiency or ~80-times the value of KDP (potassium dihydrogen phosphate). The nonlinear performance of \(5\text{i}\) is the highest reported for TRF-derived...
NLO chromophores so far and underlines the efficiency of the proposed donor-acceptor-donor design.

3. Conclusion

Systematic investigations on the thiophene ring-fragmentation reaction focusing on improved selectivity as well as enhanced efficiency have been presented. The application of state of the art inline reaction monitoring technique revealed novel insights to fragmentation on-set temperatures and reaction kinetics. As a result, reliable synthetic procedures for lab-scale (Na2SO3 method) as well as mid- to large-scale (flow chemistry) were established. In addition a new design concept for ene-yne based NLO materials was developed, which strengthens the relevance of TRF products in the field of functional organic materials.

4. Experimental section

4.1. Synthesis

4.1.1. General procedures and methods

All reactions were performed in oven-dried glassware. Reagents were purchased from common commercial sources and used without prior purification. Anhydrous solvents were prepared by filtration through drying columns. Column chromatography was performed on silica 60 (40–63 μm) using distilled solvents as given. Melting points were recorded on an Automated Melting Point System and are corrected.

NMR spectra were recorded at 400 MHz for 1H and 100 MHz for 13C for all target compounds (ene-yne) and at 200 MHz for 1H and 50 MHz for 13C for intermediates. Data for 1H NMR are reported as follows: chemical shift in parts per million (ppm) from TMS (tetramethylsilane) with the residual solvent signal as an internal reference (CDCl3 δ = 7.26 ppm), multiplicity (s = singlet, d = doublet, t = triplet and m = multiplet), coupling constant in Hz and integration. 13C NMR spectra are reported in ppm from TMS using the central peak of the solvent as reference (CDCl3 δ = 77.0 ppm); multiplicity with respect to proton (deduced from APT experiments, s = quaternary C, d = CH, t = CH2, q = CH3).

4.1.2. General procedure for the halogen dance (HD) reaction

To a solution of diisopropylamine (DIPA, 1.4 eq.) in anhydrous THF under argon n-BuLi (1.2 eq.) was slowly added at −30 to −40 °C. After 30–60 min the thiophene species (1, 1.0 eq.) was added in anhydrous THF at −70 °C and the reaction stirred for 1.5–2 h. Subsequently, the appropriate silyl chloride (1.2 eq.) was added as a solution in anhydrous THF and the mixture stirred at rt overnight. The reaction was poured on water, extracted with Et2O, the organic phases were dried over anhydrous Na2SO4 and concentrated under reduced pressure.

4.1.3. General procedure for the thiophene ring-fragmentation (TRF) reaction

To a solution of 2a-c (1.0 eq.) in anhydrous Et2O (−0.2 M) under argon atmosphere at −40 to −60 °C n-BuLi (1.1 eq.) was injected dropwise. After the addition the reaction was immediately warmed to rt, stirred for 30 min and again cooled to −40 °C. At this point the addition of first Na2SO3 (1.2 eq.) then Mel (1.5 eq.) was accomplished and the temperature subsequently raised to rt. After a reaction time of 20–60 min the mixture was poured on water, extracted with Et2O, the organic phases were washed with brine, dried over anhydrous Na2SO4 and concentrated in vacuo. Purification was performed by column chromatography (light petroleum).

4.1.4. General procedure for CuAAC

To a suspension of 3a (1.2 eq.), azide (1.0 eq.), Na ascorbate (0.4 eq.) and CuSO4·SH2O (0.2 eq.) in t-BuOH/H2O (1:1, −0.4 M) in a microwave reaction vial was added KF (1.4 eq.) at room temperature. Subsequently, the reaction vial was sealed and heated to 150 °C for 30 min in a reaction microwave. Then the reaction mixture was poured on H2O and extracted with Et2O. The combined organic layers were washed with brine, dried over anhydrous Na2SO4 and concentrated under reduced pressure. Final purification was accomplished by column chromatography.

4.1.5. Synthetic details

The syntheses of 2-bromo-5-methylthiophene (1a), 2-bromo-5-phenylthiophene (1b), 2-bromo-5-[2-(trimethylsilyl)
3-bromo-5-methyl-2-(trimethylsilyl) thiophene (2a), 1-azido-4-methoxybenzene (4i), 1-azido-4-(methylthio)benzene (4ii) and 4-azido-NN-dimethylbenzenamine (4iii) were performed according to published protocols.

14.1.1. (1,1-Dimethylthio)dimethyl(32)-4-(methylthio)-3-penten-1-yn-1-ylsilane 3b

Starting from 2b (583 mg, 2.0 mmol), n-BuLi (0.9 ml, 2.2 mmol, 2.5 M in hexanes), Na₂SO₃ (303 mg, 2.4 mmol) and Mel (426 mg, 3.0 mmol) 3b (370 mg, 82%) was isolated as a yellow low melting solid after a reaction time of 60 min at rt after the addition of Mel. ¹H NMR (400 MHz, CDCl₃): δ = 5.43 (s, 1H), 2.36 (s, 3H), 2.07 (s, 3H), 0.97 (s, 0H), 0.13 (s, 6H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 149.4 (s), 102.9 (d), 102.3 (s), 99.5 (s), 26.1 (q), 22.3 (q), 16.6 (s), 14.0 (q), −4.5 (q) ppm. Anal. Calcld for C₄H₉Si₂: m/z 272.1284 [M + H]⁺. Found: MS (APCI, TOF): m/z 272.1281 [M + H]⁺.

14.1.2. Tris(1-methylthio)[(3Z)-4-(methylthio)-3-penten-1-yn-1-ylsilane 3c

Starting from 2c (500 mg, 1.5 mmol), n-BuLi (0.65 ml, 1.7 mmol, 2.5 M in hexanes), Na₂SO₃ (277 mg, 1.8 mmol) and Mel (319 mg, 2.3 mmol) 3c (302 mg, 75%) was isolated as colorless low melting solid after a reaction time of 60 min at rt subsequently to the addition of the methyl-species. ¹H NMR (400 MHz, CDCl₃): δ = 5.46 (s, 1H), 2.36 (s, 3H), 2.08 (s, 3H), 1.10 (m, 2H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 149.0 (s), 103.4 (s), 103.2 (d), 97.6 (s), 22.2 (q), 18.7 (q), 14.0 (q), 11.3 (d) ppm. Anal. Calcld for C₄H₉Si₂: m/z 269.1754 [M + H]⁺. Found: MS (APCI, TOF): m/z 269.1746 [M + H]⁺.

14.1.3. Trimethyl[(3Z)-4-(methylthio)-4-phenyl-3-buten-1-yn-1-ylsilane 3d

Starting from 2d (623 mg, 2.0 mmol), n-BuLi (0.9 ml, 2.2 mmol, 2.5 M in hexanes), Na₂SO₃ (303 mg, 2.4 mmol) and Mel (426 mg, 3.0 mmol) 3d (397 mg, 81%) was isolated as yellow oil after a reaction time of 30 min at rt after the addition of Mel. ¹H NMR (400 MHz, CDCl₃): δ = 7.41–7.33 (m, 5H), 5.76 (s, 1H), 2.13 (s, 3H), 0.26 (s, 9H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 152.6 (s), 138.2 (d), 128.7 (d), 128.5 (d), 128.0 (d), 107.5 (d), 103.2 (s), 102.2 (s), 16.1 (q), 0.0 (q) ppm. Anal. Calcld for C₅H₄Si₂: m/z 247.0971 [M + H]⁺. Found: MS (ESI, TOF): m/z 247.0958 [M + H]⁺.

14.1.4. (3Z)-3-(Methylthio)-3-hexen-1,5-diyne, 1,6-diyi bis(trimethylsilane) 3e

Starting from 2e (331 mg, 1.0 mmol), n-BuLi (0.45 ml, 1.1 mmol, 2.5 M in hexanes), Na₂SO₃ (151 mg, 1.2 mmol) and Mel (213 mg, 1.5 mmol) 3e (206 mg, 77%) was obtained as slightly orange low melting solid after a reaction time of 30 min at rt subsequently to the addition of Mel. ¹H NMR (400 MHz, CDCl₃): δ = 5.87 (s, 1H), 2.42 (s, 3H), 0.22 (m, 18H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 133.9 (s), 111.3 (d), 109.1 (s), 104.1 (s), 100.9 (s), 99.4 (s), 15.7. (q), 0.1 (q) ppm. Anal. Calcld for C₆H₄Si₂: m/z 267.1054 [M + H]⁺. Found: MS (ESI, TOF): m/z 267.1045 [M + H]⁺.

14.1.5. Isomerization procedure towards trimethyl[(3E)-4- (methylthio)-3-penten-1-yn-1-ylsilane 3f

Starting from 2f (220 mg, 1.2 mmol, 1.0 eq.) was dissolved in a solution of I₂ (1.2 ml, 12.0 mol%) in CHCl₃ (7 ml) in NMR glass tubes and irradiated with an external light source for 20 min (IntelliRay 600, 500 intensity) resulting in a relative E-isomer content of 86%. Subsequently, the mixture was diluted with CHCl₃ and extracted with an aqueous Na₂SO₄ solution. The organic layer was dried over anhydrous Na₂SO₄ and the solvent removed under reduced pressure. Column chromatography (light petroleum) yielded compound 3f (167 mg, 76%) as slightly yellow oil. ¹H NMR (400 MHz, CDCl₃): δ = 5.12 (s, 1H), 2.25 (s, 3H), 2.14 (s, 3H), 0.19 (s, 9H) ppm. ¹³C NMR (100 MHz, CDCl₃): δ = 150.9 (s), 102.5 (s), 99.0 (d), 97.7 (s), 20.6 (q), 14.7 (q), 0.1 (q) ppm. Anal. Calcld for C₆H₄Si₂: m/z 185.0815 [M + H]⁺. Found: MS (APCI, TOF): m/z 185.0810 [M + H]⁺.
4.1.16. 4-[(1Z)-2-(Methylthio)-1-propen-1-y1]-1-(4-methoxyphenyl)-1H-1,2,3-triazol Sii

Starting from 3a (1.55 g, 8.4 mmol), 4i (1.04 g, 7.0 mmol), Na ascorbate (0.56 g, 2.8 mmol), CuSO4·5H2O (0.35 g, 1.4 mmol) and KF (0.57 g, 9.8 mmol) Sii (1.50 g, 82%) was obtained after column chromatography (light petroleum/Et2O 1:1). 1H NMR (400 MHz, CD2Cl2):  δ = 8.31 (s, 1H), 7.66 (d, J = 9.0 Hz, 2H), 7.04 (d, J = 9.0 Hz, 2H), 6.61 (d, J = 1.1 Hz, 1H), 3.86 (s, 3H), 2.42 (s, 3H), 2.27 (d, J = 1.1 Hz, 3H) ppm. 13C NMR (100 MHz, CD2Cl2):  δ = 160.3 (s), 145.6 (s), 135.9 (s), 131.2 (s), 122.6 (d), 120.6 (d), 115.2 (d), 115.1 (d), 56.2 (q), 23.8 (q), 14.7 (q) ppm. Anal. Calcd for C14H18N4S: m/z 278.0783 [M + H]+; Found: MS (ESI, TOF): m/z 278.0780 [M + H]+.

4.1.17. 4-[(1Z)-2-(Methylthio)-1-propen-1-y1]-1-(4-methylthio phenyl)-1H-1,2,3-triazol Siii

Starting from 3a (288 mg, 1.56 mmol), 4ii (215 mg, 1.30 mmol), Na ascorbate (103 mg, 0.52 mmol), CuSO4·5H2O (65 mg, 0.26 mmol) and KF (106 mg, 1.82 mmol) Siii (121 mg, 34%) was obtained after column chromatography (light petroleum/Et2O 3:2). 1H NMR (400 MHz, CD2Cl2):  δ = 8.35 (s, 1H), 7.69 (d, J = 8.6 Hz, 2H), 7.39 (d, J = 8.6 Hz, 2H), 6.62 (s, 1H), 2.54 (s, 3H), 2.42 (s, 3H), 2.22 (s, 3H) ppm. 13C NMR (100 MHz, CD2Cl2):  δ = 145.7, 140.2, 136.3, 134.8, 127.6, 121.3, 120.4, 114.9, 23.8, 16.0, 14.7 ppm. Anal. Calcd for C13H15N3OS: m/z 278.0780 [M + H]+; Found: MS (ESI, TOF): m/z 278.0780 [M + H]+.

4.1.18. NN-dimethyl-4-[(1Z)-2-(methylthio)-1-propen-1-y1]-1H-1,2,3-triazol-1-yl-benzeneamine Siii

Starting from 3a (288 mg, 1.56 mmol), 4i (211 mg, 1.30 mmol), Na ascorbate (103 mg, 0.52 mmol), CuSO4·5H2O (65 mg, 0.26 mmol) and KF (106 mg, 1.82 mmol) Siii (203 mg, 57%) was obtained after column chromatography (light petroleum/Et2O 3:2). 1H NMR (400 MHz, CD2Cl2):  δ = 8.26 (s, 1H), 7.56 (d, J = 9.0 Hz, 2H), 6.79 (d, J = 9.0 Hz, 2H), 6.61 (s, 1H), 3.01 (s, 6H), 2.41 (s, 3H), 2.26 (s, 3H) ppm. 13C NMR (100 MHz, CD2Cl2):  δ = 151.1 (s), 145.3 (s), 135.4 (s), 127.3 (s), 122.2 (d), 120.5 (d), 115.4 (d), 112.7 (d), 40.8 (q), 23.8 (q), 14.7 (q) ppm. Anal. Calcd for C14H18N4S: m/z 275.1325 [M + H]+; Found: MS (ESI, TOF): m/z 275.1323 [M + H]+.

4.2. IR monitoring

The ATR-IR fibre system consisted of a ReactIRTM 15 spectrometer equipped with an MCT (mercury cadmium telluride) detector (Mettler Toledo) connected to a DiComp Probe (Mettler Toledo, dimensions: 6.3 mm DSub AgX DiComp, 8 inches (203 mm) wetted length with a 1.5 m total length of AgX fibercoupid, optical window: 2500 to 650 cm−1, temperature range: −80 to 180 °C, pH range: 1–14, wetted materials: alloy C276, diamond, gold). Spectra were recorded over the duration of the entire reaction at a spectral resolution of 4 cm−1, averaging 76 scans yielding a temporal resolution of 30 s. The fibre probe was integrated in a double-walled cooling reactor (−10 mL volume) via feed-trod equipped with an argon inlet and a septum. The reaction vessel was charged with anhydrous solvent (Et2O) and cooled by cryostat (Julabo) to −60 °C. After a steady temperature in the reactor was reached the background spectrum was recorded, the measurement started and the lithium species added. Subsequently the respective reactant was rapidly added via a syringe (concentrations and equivalents identi cal to the preparative experiments).

4.3. Flow chemistry

Screening experiments in the flow were carried out using three New Era NE-1000 syringe pumps. 2a (4.98 g, 20.0 mmol) and n-dodecane (1.25 g) were dissolved in anhydrous Et2O (200 mL) and a 50 mL (60 mL) syringe was filled with the solution. Methyl iodide (4.82 g, 33.9 mmol) was dissolved in anhydrous Et2O (100 mL) and a 20 mL (24 mL) syringe was filled with the solution. A 10 mL syringe was filled with n-butyllithium (1.6 mol/L in hexanes). Na2SO3 (3.16 g, 25 mmol) was dissolved in deionized water (100 mL) and sixteen screw-cap vials were charged with Na2SO3 solution (1.35 mL each). The syringes were connected to the reactor inlets via Luer-Slip adapters as follows: starting material to inlet 1; n-butyllithium to inlet 2 and Mel to inlet 3. The chip reactor was placed on the FlowChiller® and the temperature was monitored. The outlet tube was placed in a waste bottle. Then 2 mL of every solution were pushed into the system. The desired flow rates were entered into the pumps. After starting the pumps, the dead volume time was awaited. Then the outlet tube was placed in the first vial and two subsequent samples were collected. Upon completion the vial was screwed tight and shaken vigorously. In such manner four sets of experiments were conducted at room temperature, 0 °C, −20 °C and −40 °C. Preparation of the vials and sample collection was conducted as described above. For GC analysis 256 μL of organic layer from every sample was transferred to a GC vial, diluted with 744 μL ethyl acetate, and analyzed. For the pre-scale experiment, reagents were prepared in the same way, whereas the syringe pumps were replaced with continuous pumps (Syrris Africa) and the reaction time was prolonged. After separation of the layers the diethyl ether was evaporated under reduced pressure. Purification of the crude product was accomplished via column chromatography (MPLC, light petrol, then ethyl acetate), yielding 1.258 g (56%) of pure product 3a as a yellowish oil.

4.4. X-ray diffraction

Diffraction data of single crystals of Si (two polymorphs), Sii and Siii were collected on a Bruker KAPPA APEX II diffractometer system equipped with a CCD detector at 100 K under a dry stream of nitrogen using fine sliced ϕ- and ω-scans. Data were reduced using SAINT-Plus® and corrected for absorption using SADABS®. The structures were solved with charge-flipping implemented in SUPERFLIP® and refined against F using Jana2006®. All non-H atoms were refined with anisotropic atomic displacement parameters. H atoms were located in difference Fourier maps and refined freely in Si (both polymorphs) and Sii. In Siii the H atoms were placed at calculated positions and refined as riding on the parent C atom.

4.5. Second harmonic generation

The second order nonlinear optical properties of the substances were screened with second harmonic measurements from powder samples, produced by grinding the sample crystals with a mortar to a particle size below <1 μm. A relative measurement of the nonlinear optical coefficients is possible with this technique since the SH efficiency scales quadratically with the nonlinear coefficient in this particle size regime. The powder samples, sandwiched between microscope slides, were irradiated with the output of an ultrafast Yb:KGW-Laser (Light Conversion, pulse duration 70 fs, average power 600 mW, repetition rate 75 MHz, wavelength 1034 nm), moderately focused with a 100 mm focusing lens. The diffusely reflected SH-radiation was collected with a NA = 0.1 lens, separated from fundamental radiation with a color filter, and spectrally analyzed with a 0.25 m grating monochromator and a photomultiplier detector. The sample plane was positioned somewhere out of the focal plane (towards the lens) so as to prevent any damage to the sample. After each measurement, the samples were carefully checked for the absence of damage or thermal modification.
Acknowledgment

This work was supported in part by the TU Wien “Innovative Projects” research funds and the Austrian Federal Ministry of Science, Research and Economy. The authors acknowledge M. Lunzer, D. Wurm, D. Koch, B. Pokorny, D. Möstl, F. Krenn and A. Kempf for supporting the synthetic experiments. The authors also thank W. Skranc for preliminary work on this topic. N. Jankowski is acknowledged for conducting the ion chromatography and E. Rosenberg for performing the high resolution mass spectrometry (HRMS). The X-ray centre of the TU Wien is acknowledged for providing access to the single-crystal diffractometer.

Appendix A. Supplementary data
