ethink ENERGY RESEARCH

Energy mapping and data collection to identify long-term opportunities for district energy systems

Lukas Kranzl

17.6.2021, Webinar UNEP DTU Partnership

Typical questions of spatial energy planning

- Which shares of heat demand can/should be supplied by district heating?
- Which levels of heat savings are economically feasible?
- Which renewable energy and waste heat sources are economically feasible to use?
- What are conclusions for zoning policies?
- How can climate neutrality be achieved in the heating and cooling sector?

⇨ Requirement for mapping of current demand and supply and future options

Energy mapping

- The role of energy mapping in district energy planning
- Key steps in the development of energy mapping across various levels of detail
- How to use heat maps for strategy development
- Best case practices, strengths and limitations
- Lessons learned & recommendations

Project background of this presentation

- Hotmaps (H2020 project, completed, www.hotmaps.eu)

  Hotmaps develops, demonstrates and disseminates a toolbox to support public authorities, energy agencies and planners in strategic heating and cooling planning at local, regional and national levels, and in line with EU policies.

- Spatial energy planning (Austrian research project, ongoing, www.waermeplanung.at)

  The goal is to develop and provide the essential basis for a roll out of spatial heat planning in Austria. Up-to-date data on building block granularity is used to develop a HEATatlas showing heat demand, site specific RES potentials as well as energy zones as the foundation for instruments of public steering.

- Comprehensive assessment for efficient heating and cooling supply according to Art 14, Energy Efficiency Directive for the case of Austria (www.Austrian-heatmap.gv.at)

- Local case studies

Mapping is a means, not an end in itself

Levels of spatial energy planning

Kerry County Council (IE)

Status Quo

- Primarily oil, LPG and el. for heating. No natural gas grid.
- 1MW Biomass CHP in most dense area of largest town
- Large tourism industry = high heat demands in summer.
- Local energy groups investigating RE-possibilities

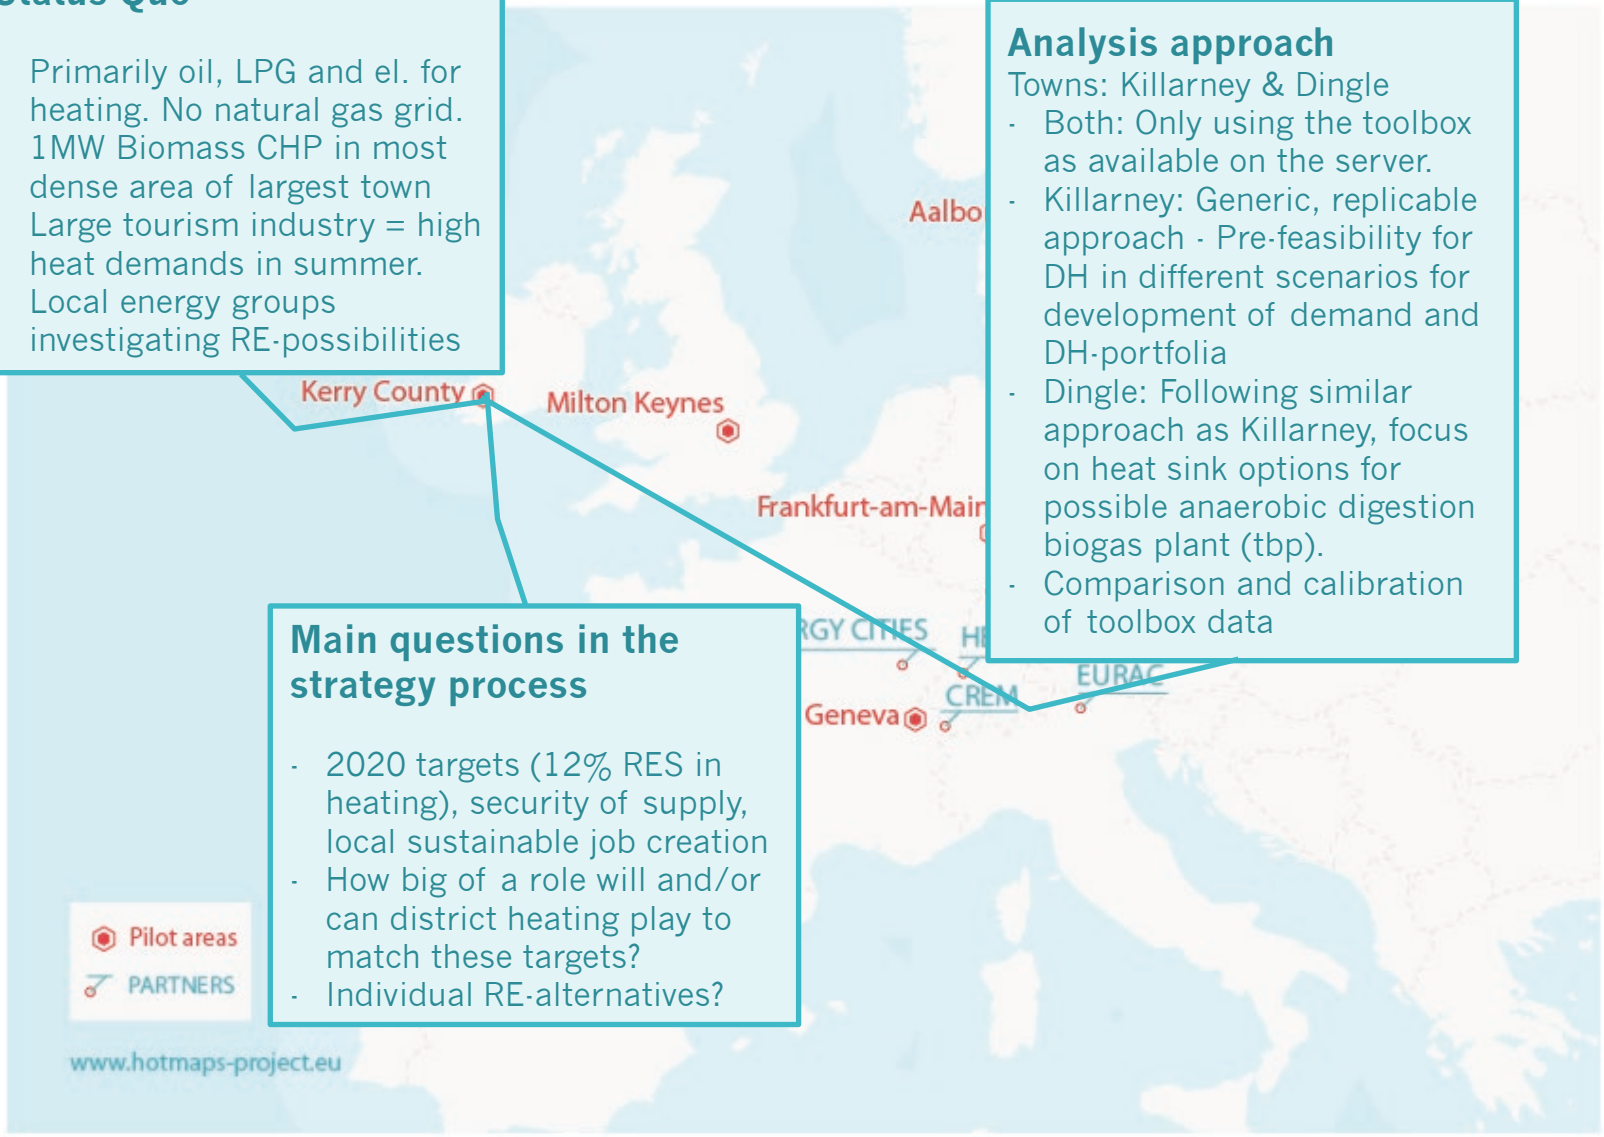
Analysis approach

Towns: Killarney & Dingle

- Both: Only using the toolbox as available on the server.
- Killarney: Generic, replicable approach · Pre-feasibility for DH in different scenarios for development of demand and DH-portfolia
- Dingle: Following similar approach as Killarney, focus on heat sink options for possible anaerobic digestion biogas plant (tbp).
- Comparison and calibration of toolbox data

Main questions in the strategy process

- 2020 targets (12% RES in heating), security of supply, local sustainable job creation
- How big of a role will and/or can district heating play to match these targets?
- Individual RE-alternatives?



Milton Keynes (UK)

Status Quo

- Primarily natural gas grid.
- Private DH (NGas CHP, bio) in Central Milton Keynes
- Densification and green-field-developments ongoing
- Currently no significant cooling needs

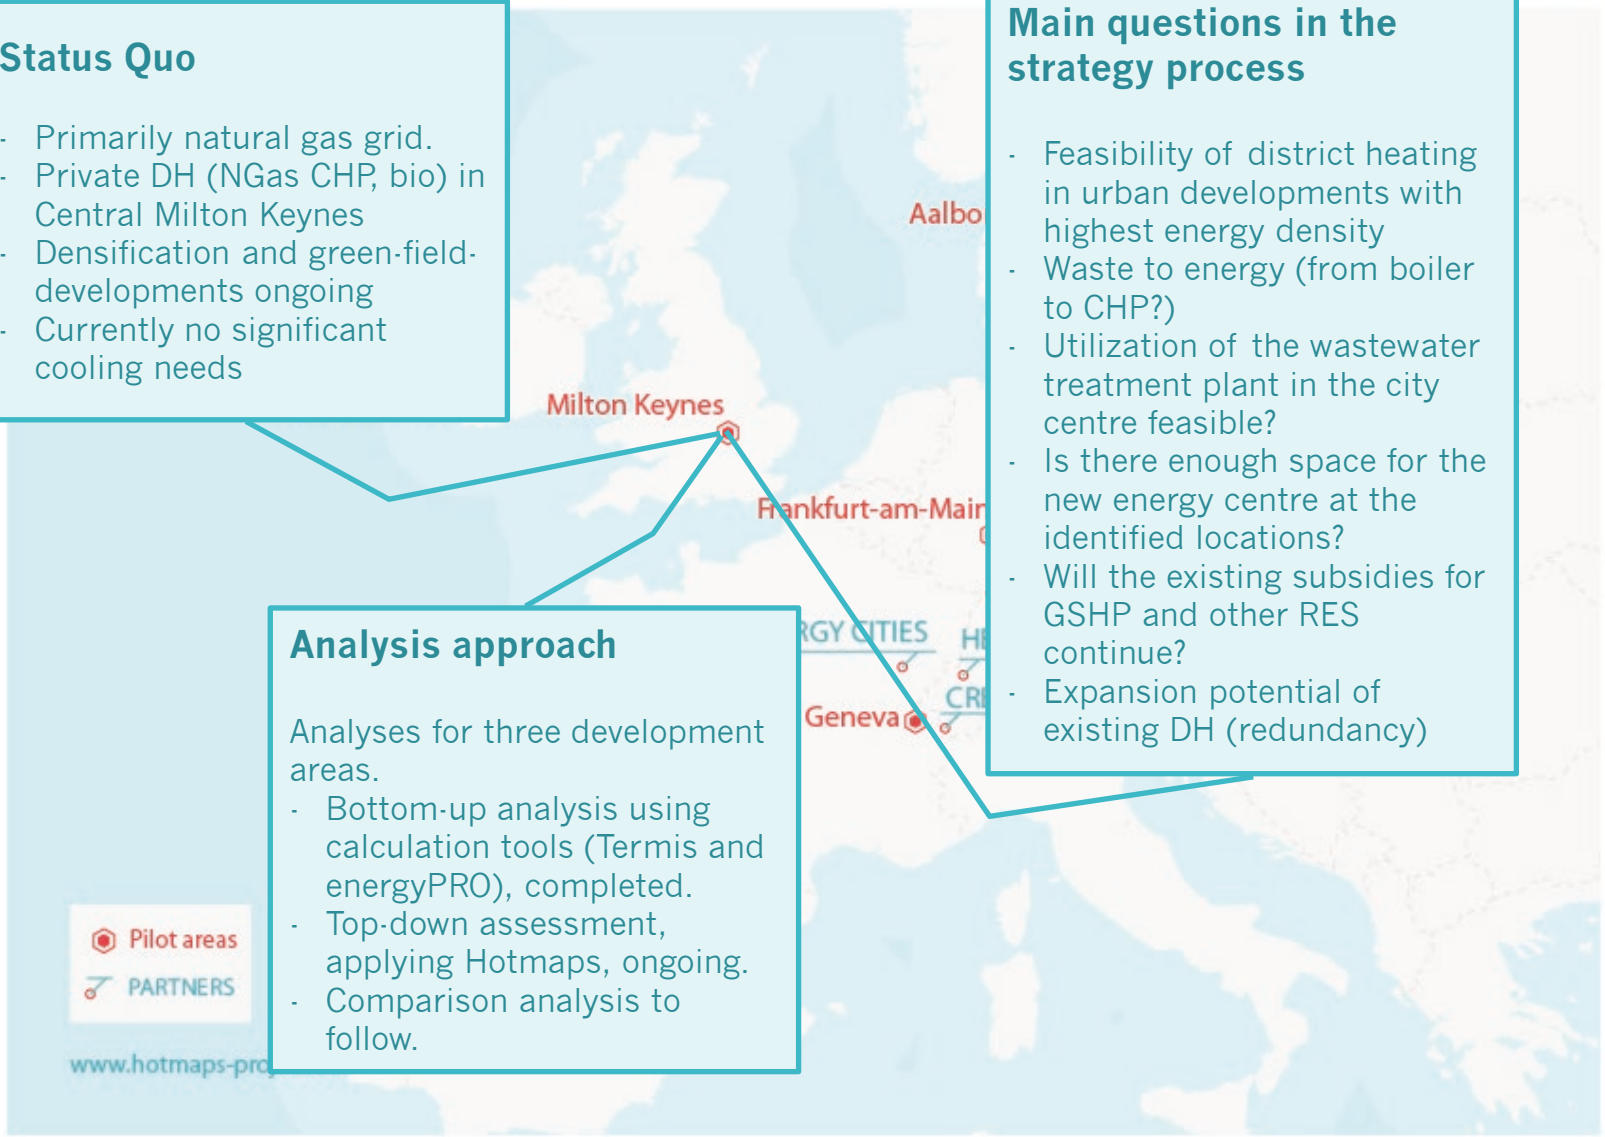
Main questions in the strategy process

- Feasibility of district heating in urban developments with highest energy density
- Waste to energy (from boiler to CHP?)
- Utilization of the wastewater treatment plant in the city centre feasible?
- Is there enough space for the new energy centre at the identified locations?
- Will the existing subsidies for GSHP and other RES continue?
- Expansion potential of existing DH (redundancy)

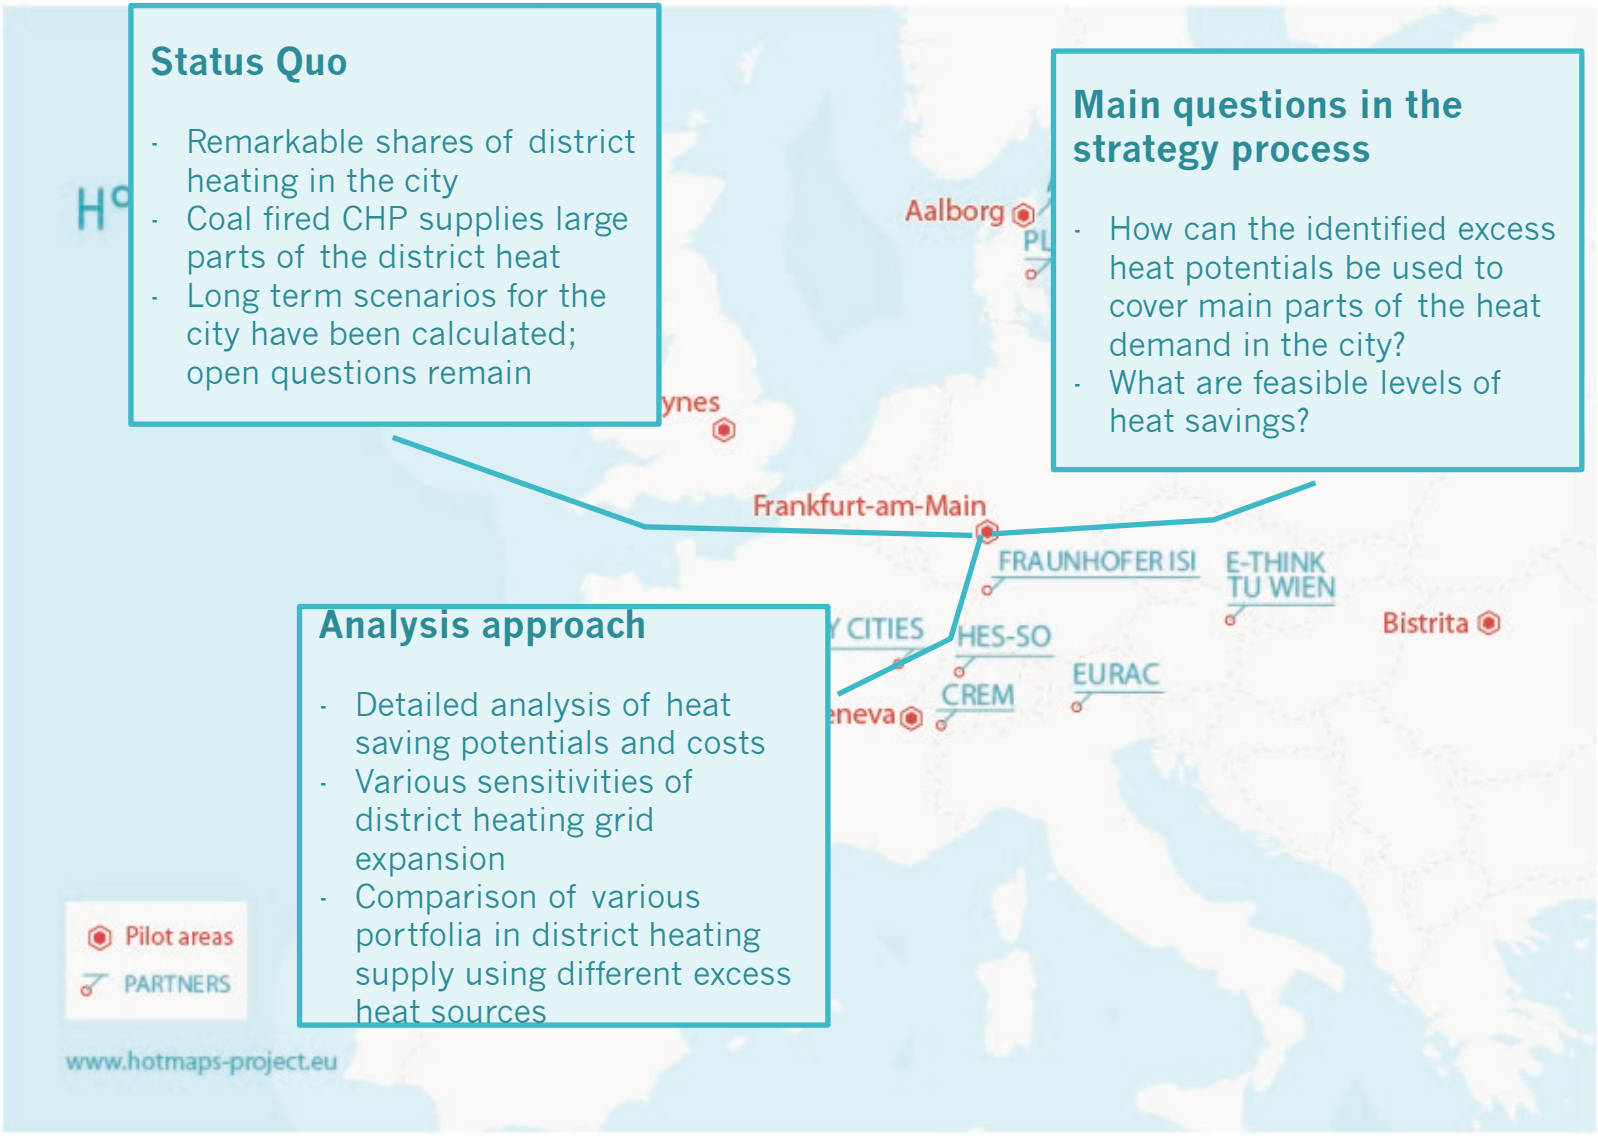
Analysis approach

Analyses for three development areas.

- Bottom-up analysis using calculation tools (Termis and energyPRO), completed.
- Top-down assessment, applying Hotmaps, ongoing.
- Comparison analysis to follow.



City of Frankfurt am Main (DE)



Status Quo

- Remarkable shares of district heating in the city
- Coal fired CHP supplies large parts of the district heat
- Long term scenarios for the city have been calculated; open questions remain

Main questions in the strategy process

- How can the identified excess heat potentials be used to cover main parts of the heat demand in the city?
- What are feasible levels of heat savings?

Analysis approach

- Detailed analysis of heat saving potentials and costs
- Various sensitivities of district heating grid expansion
- Comparison of various portfolia in district heating supply using different excess heat sources

City of Bistrita (RO)

Status Quo

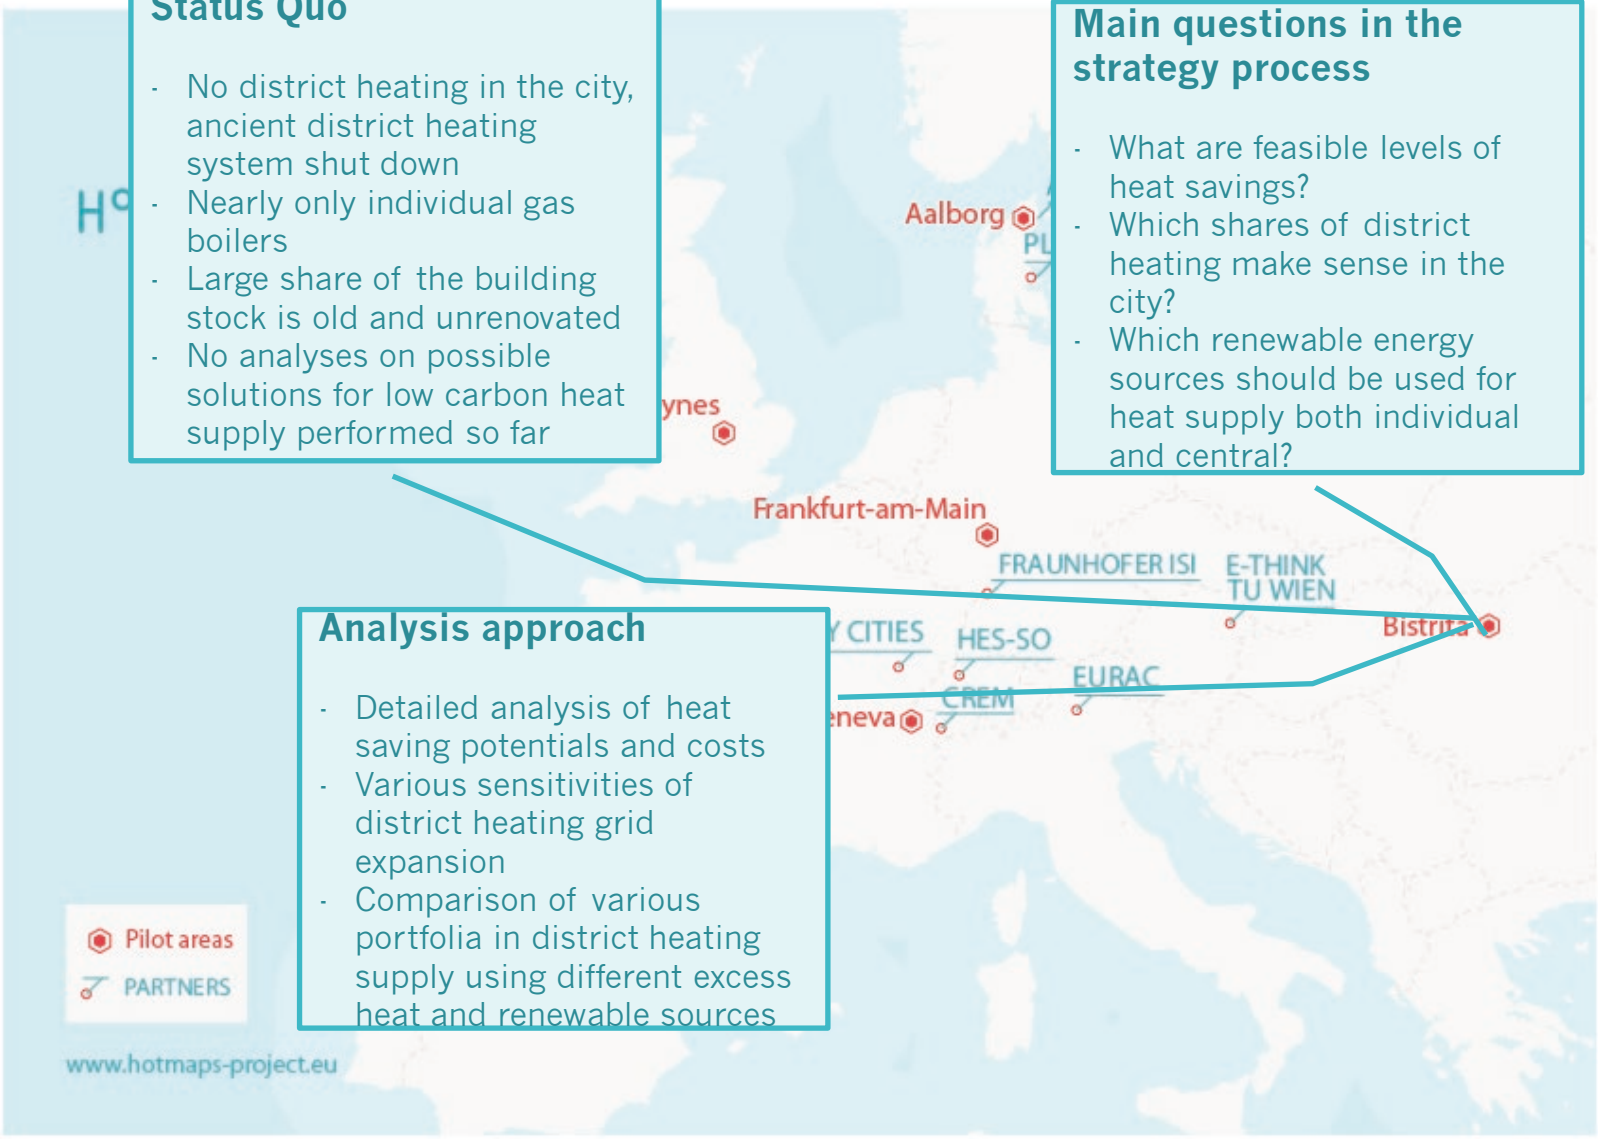
- No district heating in the city, ancient district heating system shut down
- Nearly only individual gas boilers
- Large share of the building stock is old and unrenovated
- No analyses on possible solutions for low carbon heat supply performed so far

Main questions in the strategy process

- What are feasible levels of heat savings?
- Which shares of district heating make sense in the city?
- Which renewable energy sources should be used for heat supply both individual and central?

Analysis approach

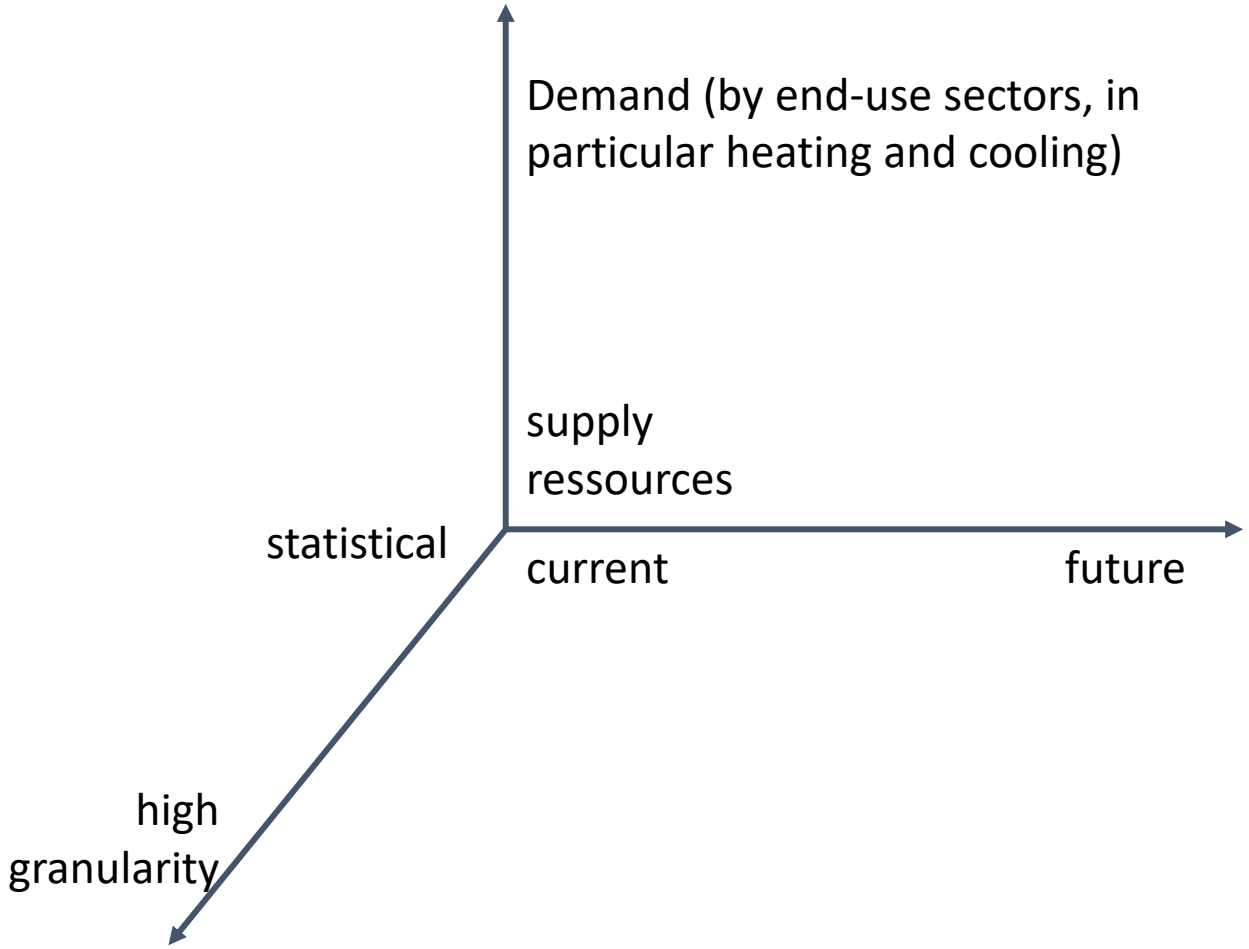
- Detailed analysis of heat saving potentials and costs
- Various sensitivities of district heating grid expansion
- Comparison of various portfolia in district heating supply using different excess heat and renewable sources



Strategy development process applied in Hotmaps

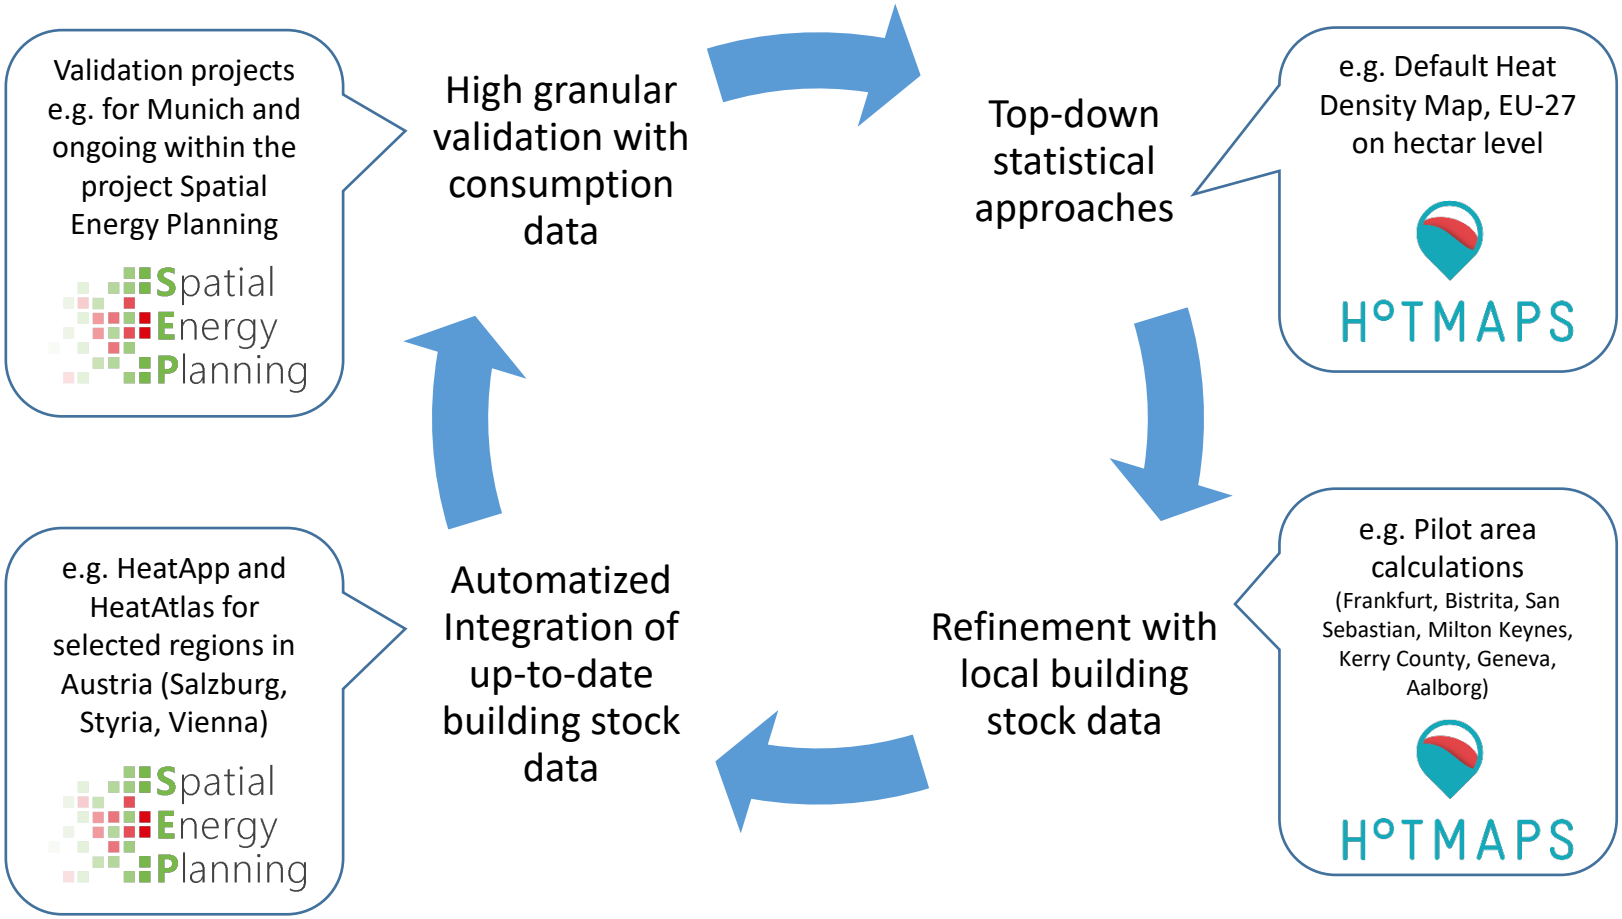
- Description of the city and analysis of stakeholders
  - Local, regional and national targets
  - Description of existing H&C system
  - Analysis of stakeholders
  - Analysis of barriers and drivers
- Mapping of demand, resources potentials and existing plants
- First stakeholder meeting
  - Discuss results of mapping and current state
  - Discuss method and scenarios to be calculated
- Setting up scenarios of future H&C
  - Compilation of economic input data
  - Calculation of various scenarios
  - Scenario assessment regarding relevant indicators
- Second stakeholder meeting
  - Discuss scenario results
  - Discuss recommendations for strategy and roadmap
- Strategy formulation

Dimensions of energy (heat) mapping



Heat mapping:

Top down approaches vs. high granularity heat maps



Schematic Hotmaps-process to derive data maps on hectar level for EU-28

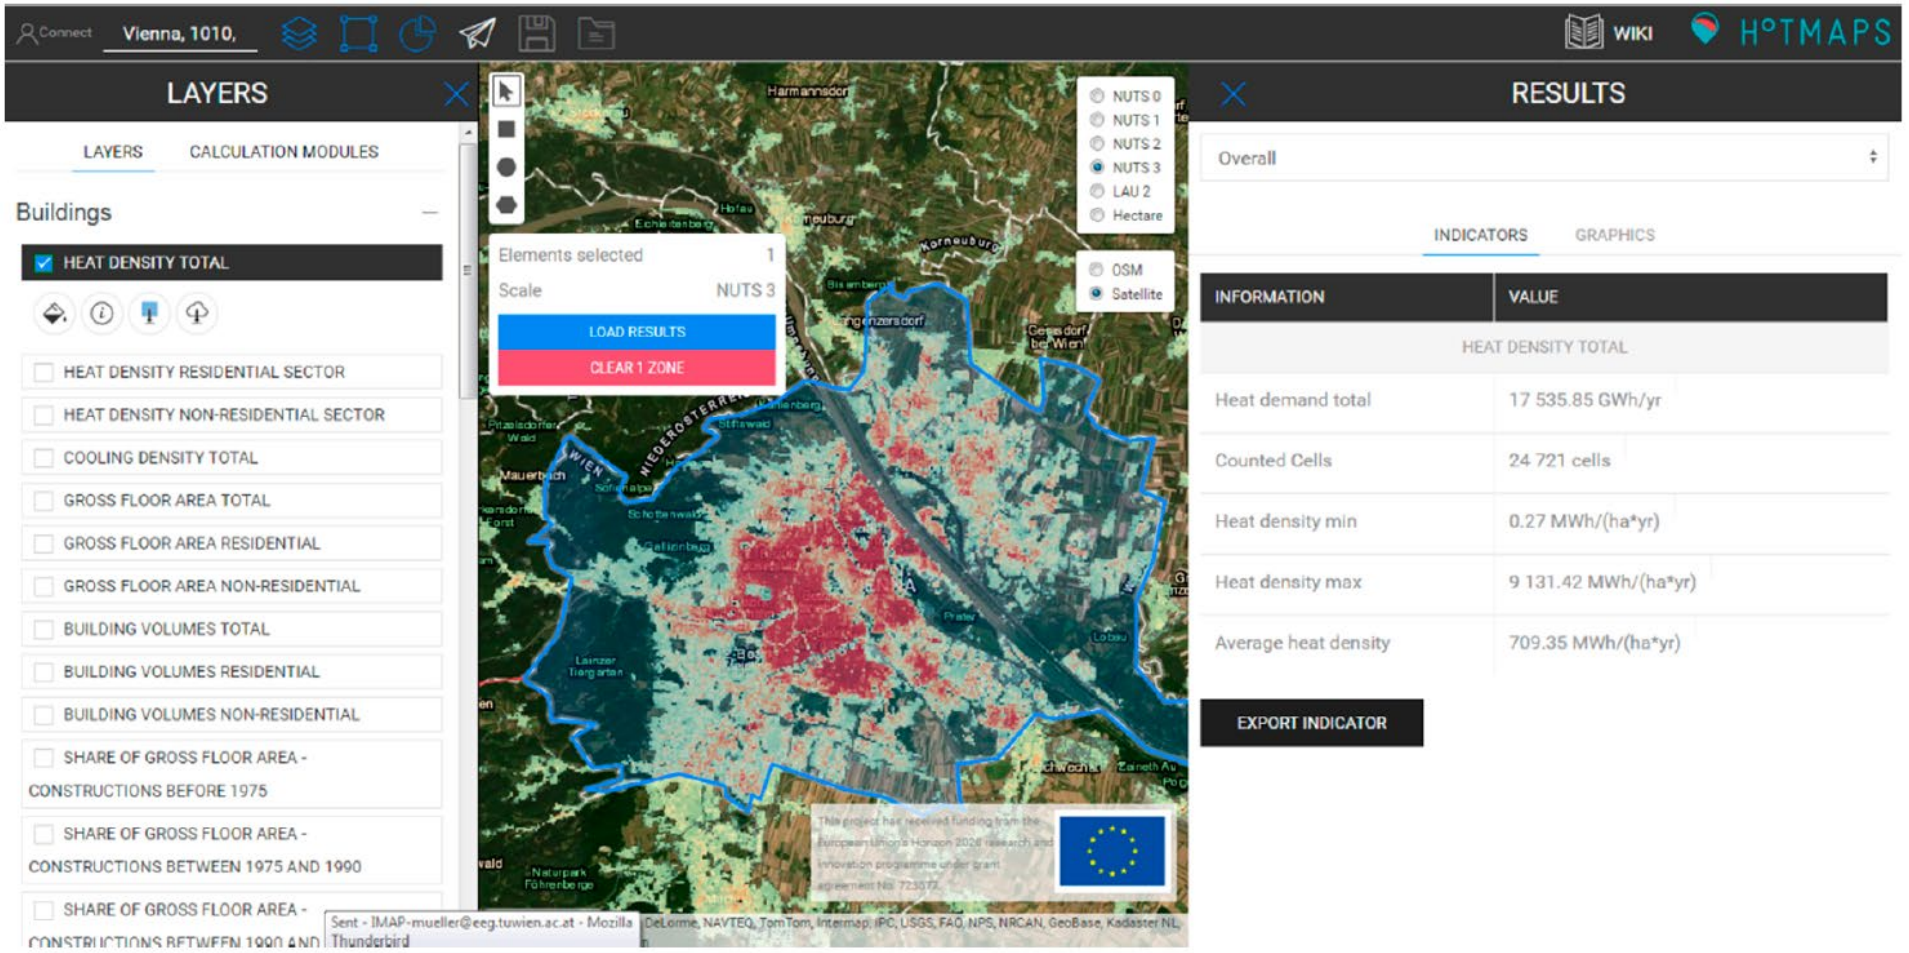
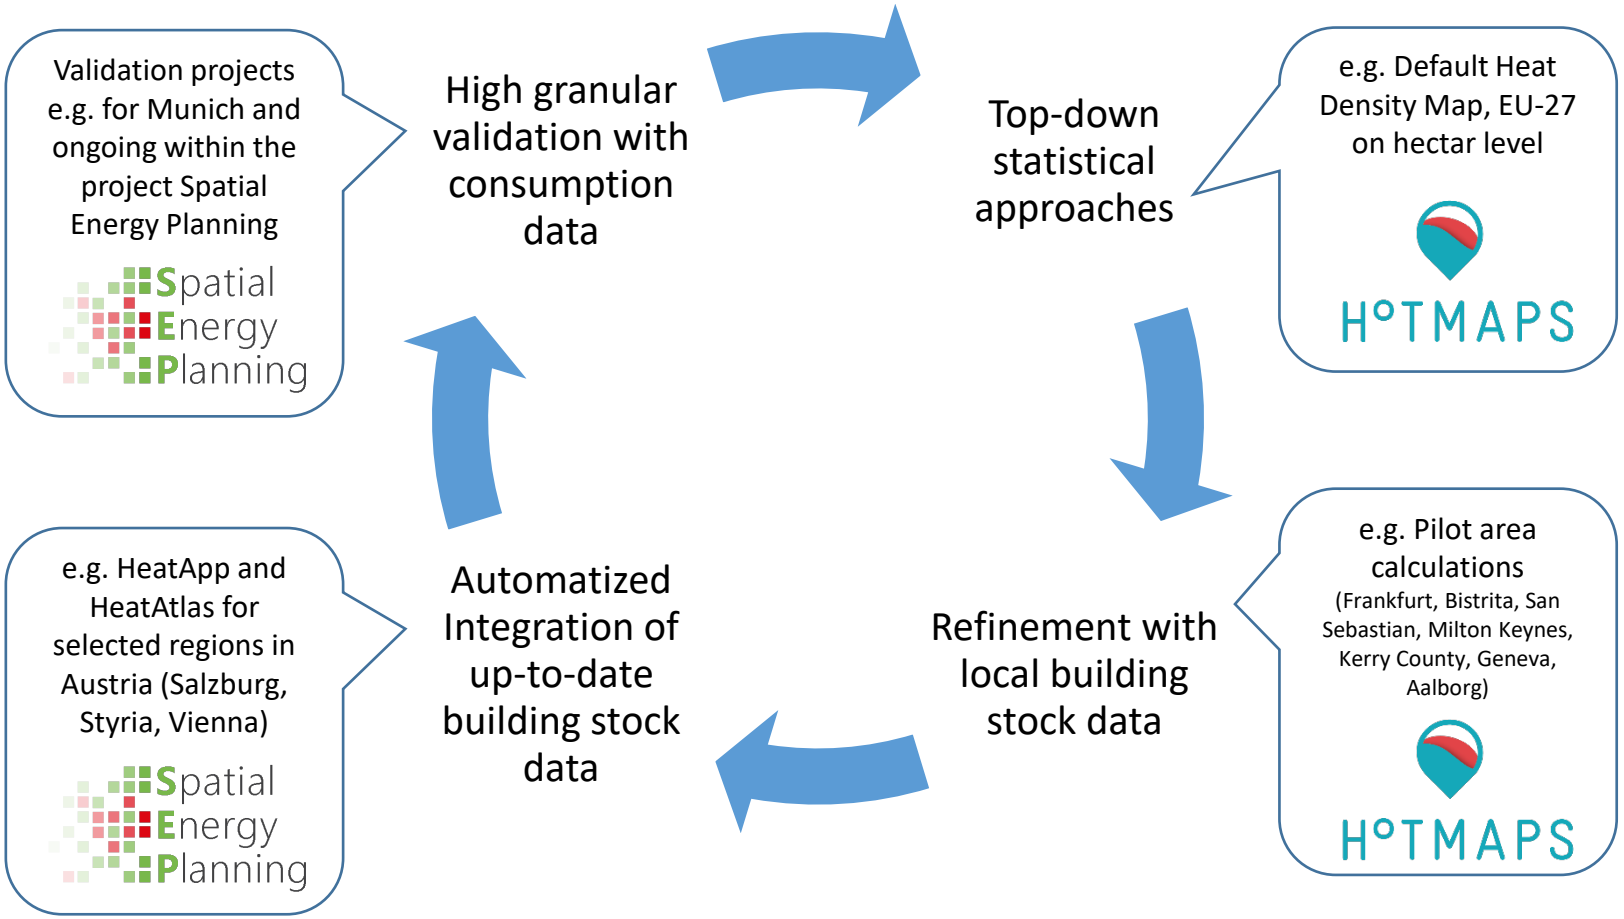
Heat demand density layer at the Hotmaps toolbox (www.hotmaps.eu)



Heat mapping:

Top down approaches vs. high granularity heat maps



Available local data and comparison with default heat density maps

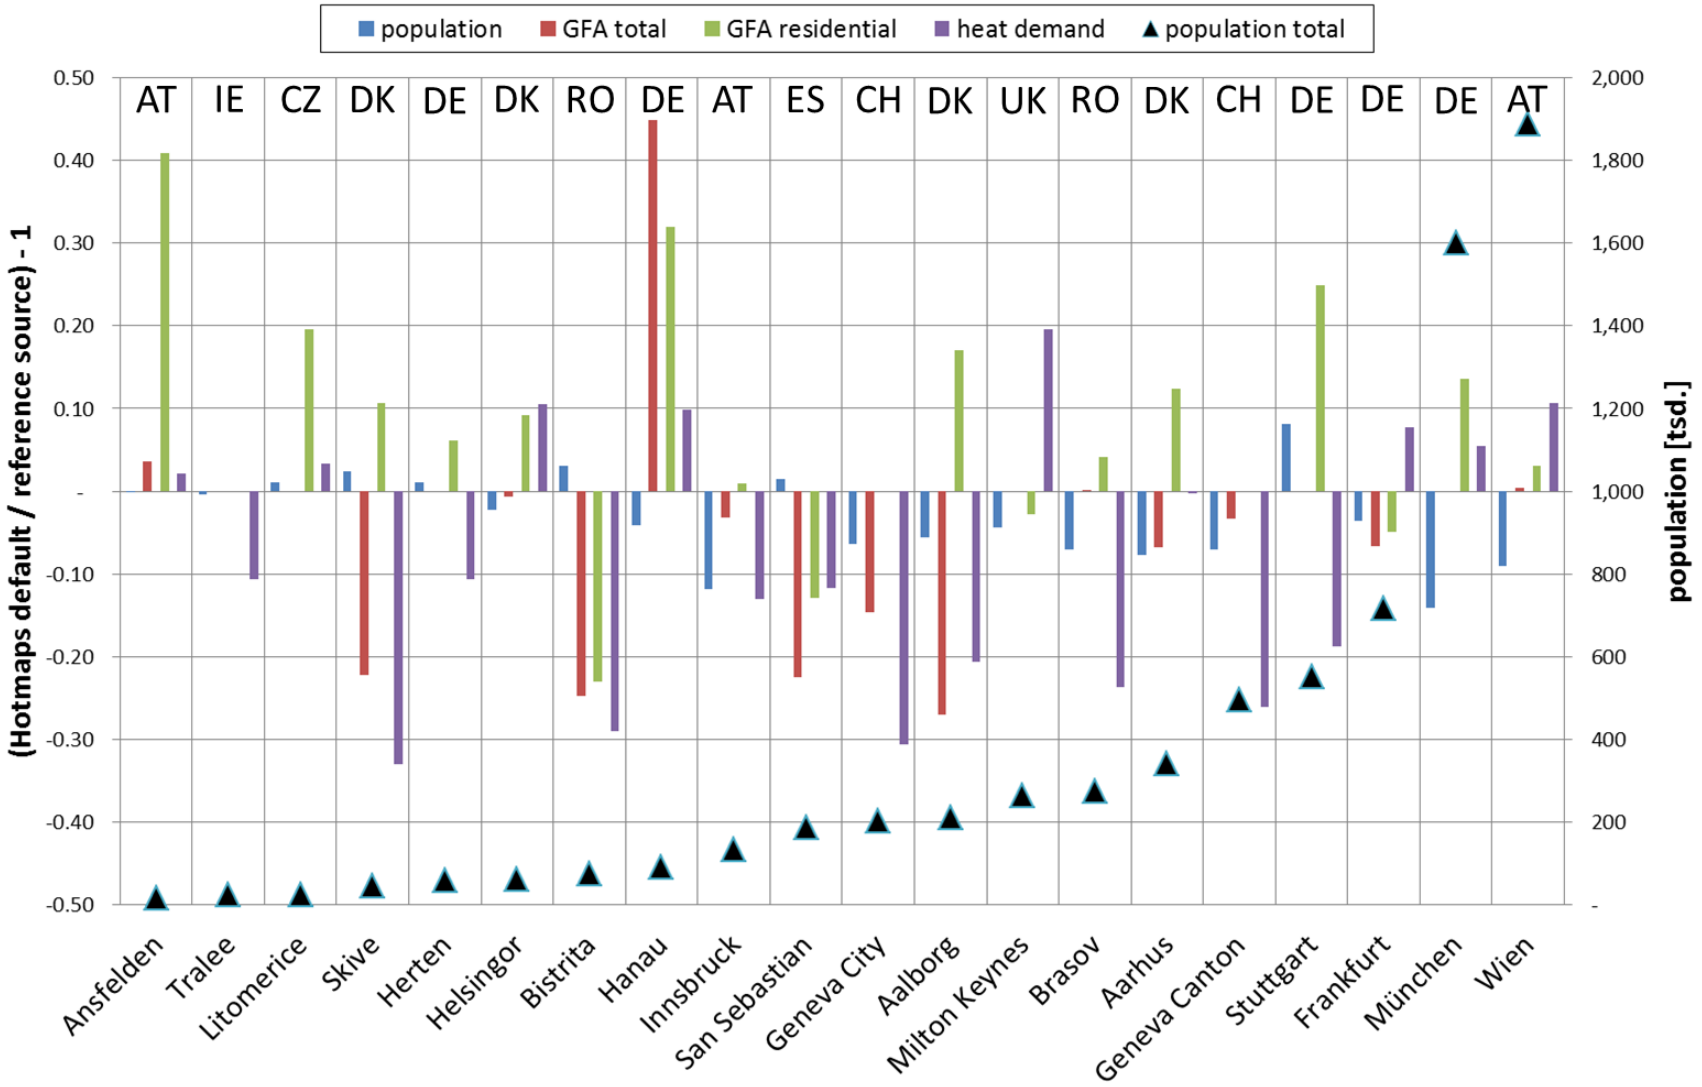
Available local data

- Knowledge available in all pilot areas
  - current energy balance at local level
  - Existing capacities in DH
- Large differences between pilot areas for several types of data: E.g.
  - Frankfurt has numerous data sets on many relevant data points
  - Bistrita has very detailed data on buildings in the city (type, age, status)
  - Milton Keynes doesn’t have detailed data of the buildings

Method for developing locally customized heat demand density layers

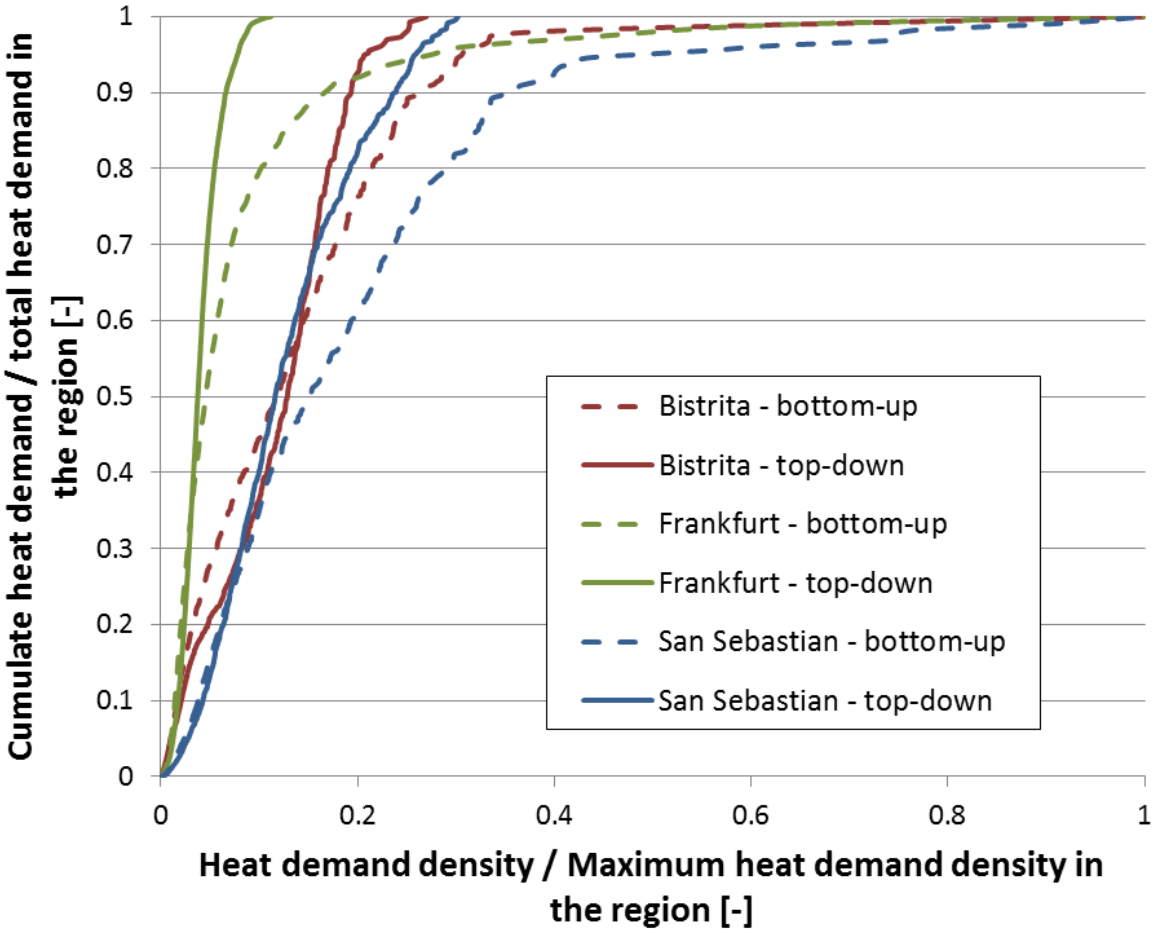
- Method used in Hotmaps for the cases Bistrita, Frankfurt and San Sebastian
- Shapefiles of all buildings in the city received from local public authorities
- These databases are joined with other data sources and further shaped to have same status of database on buildings level for all areas:
  - Type, GFA, age, location for all buildings
  - E.g. in San Sebastian with more detailed info for non-residential buildings DB
  - E.g. in Frankfurt with old version of the DB as well as with other DB on building ages
- These DBs then joined with heat demand per gross floor area values of typical building types of the respective countries (Invert/EE-Lab database), climate corrected to the PA location

Comparison of customized and default data – heat demand density



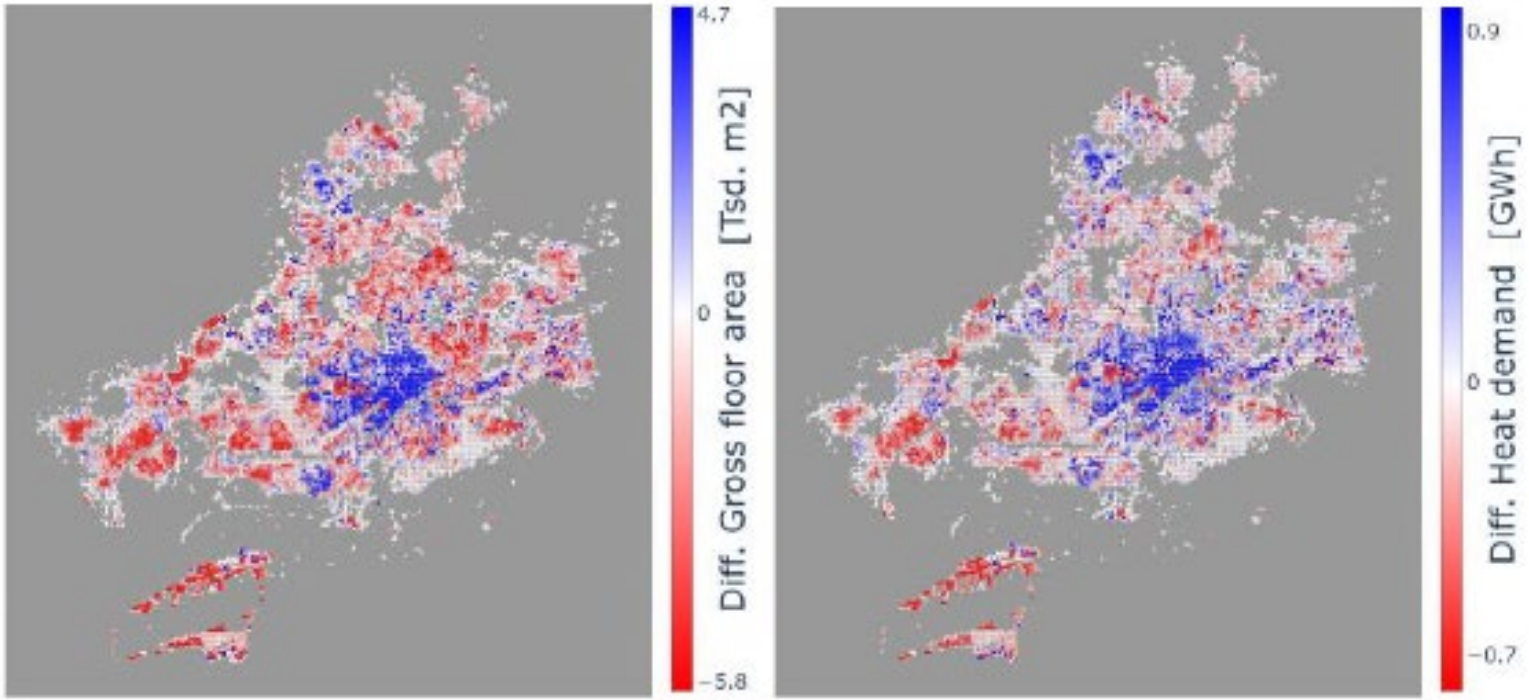
Source: Müller, A., Hummel, M., Kranzl, L., Flahnejad, M., Büchele, R., 2019, „Open source data for gross floor area and heat demand density on hectare level for EU 28", Energies

Comparison of customized and default data – heat demand density



Source: Müller, A., Hummel, M., Kranzl, L., Flahnejad, M., Büchele, R., 2019, „Open source data for gross floor area and heat demand density on hectare level for EU 28", Energies

Comparison of customized and default data



Source: Müller, A., Hummel, M., Kranzl, L., Falahnejad, M., Büchele, R., 2019, „Open source data for gross floor area and heat demand density on hectare level for EU 28", Energies

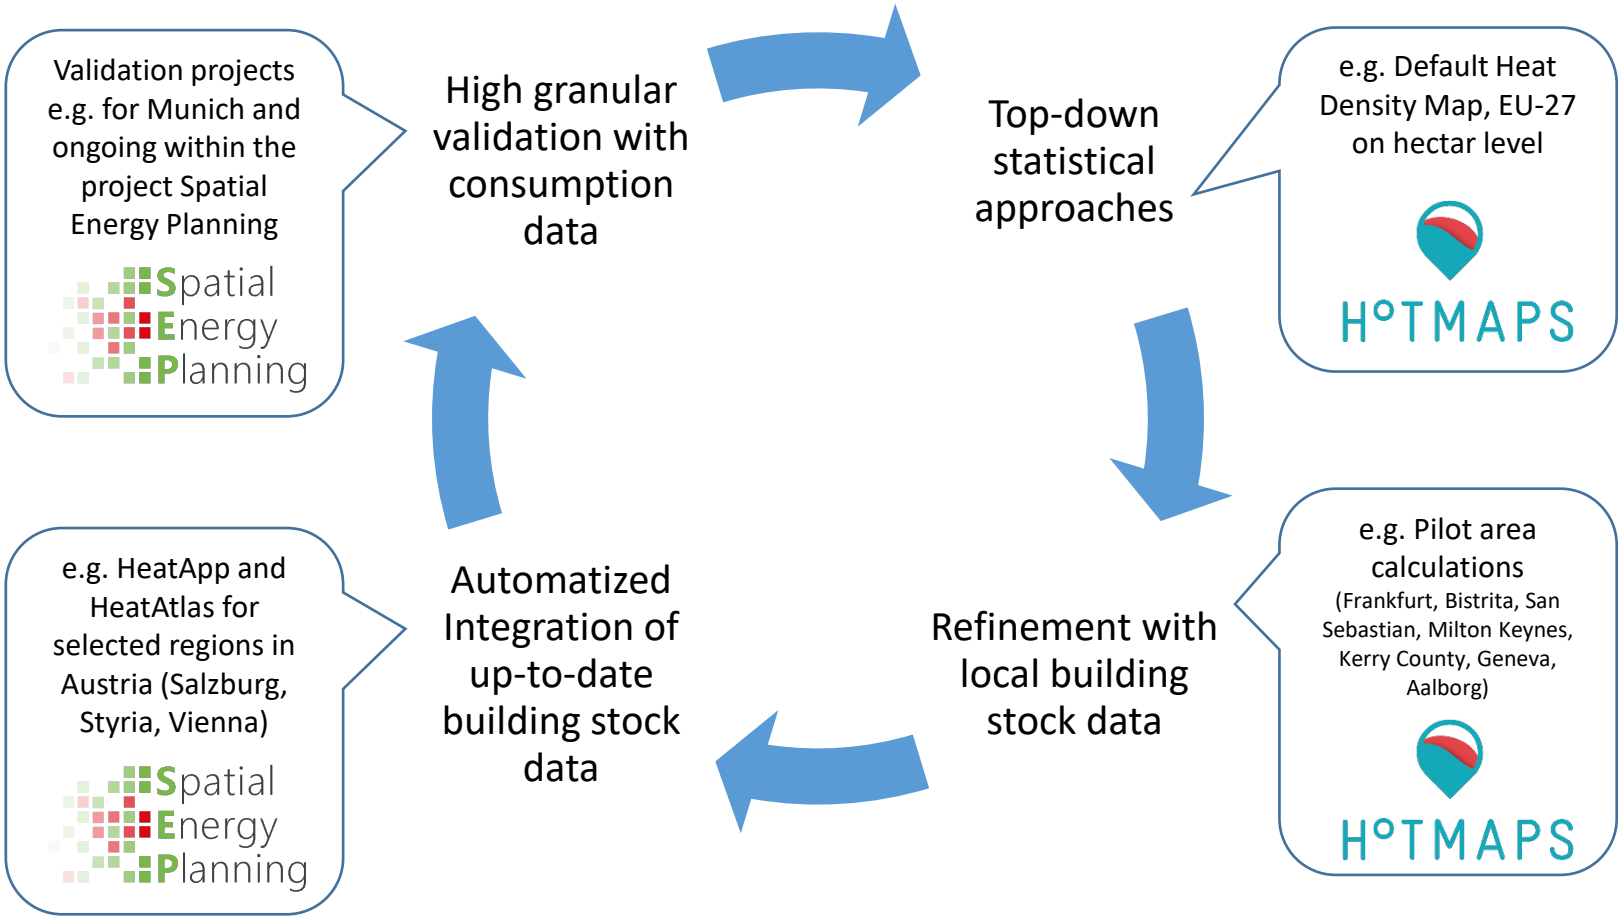
Conclusions on default data gross floor area and heat demand

- Default heat demand and gross floor area values are
  - useful for strategic purposes on aggregated level of larger regions and municipalities
  - especially valuable in locations where no detailed data is available

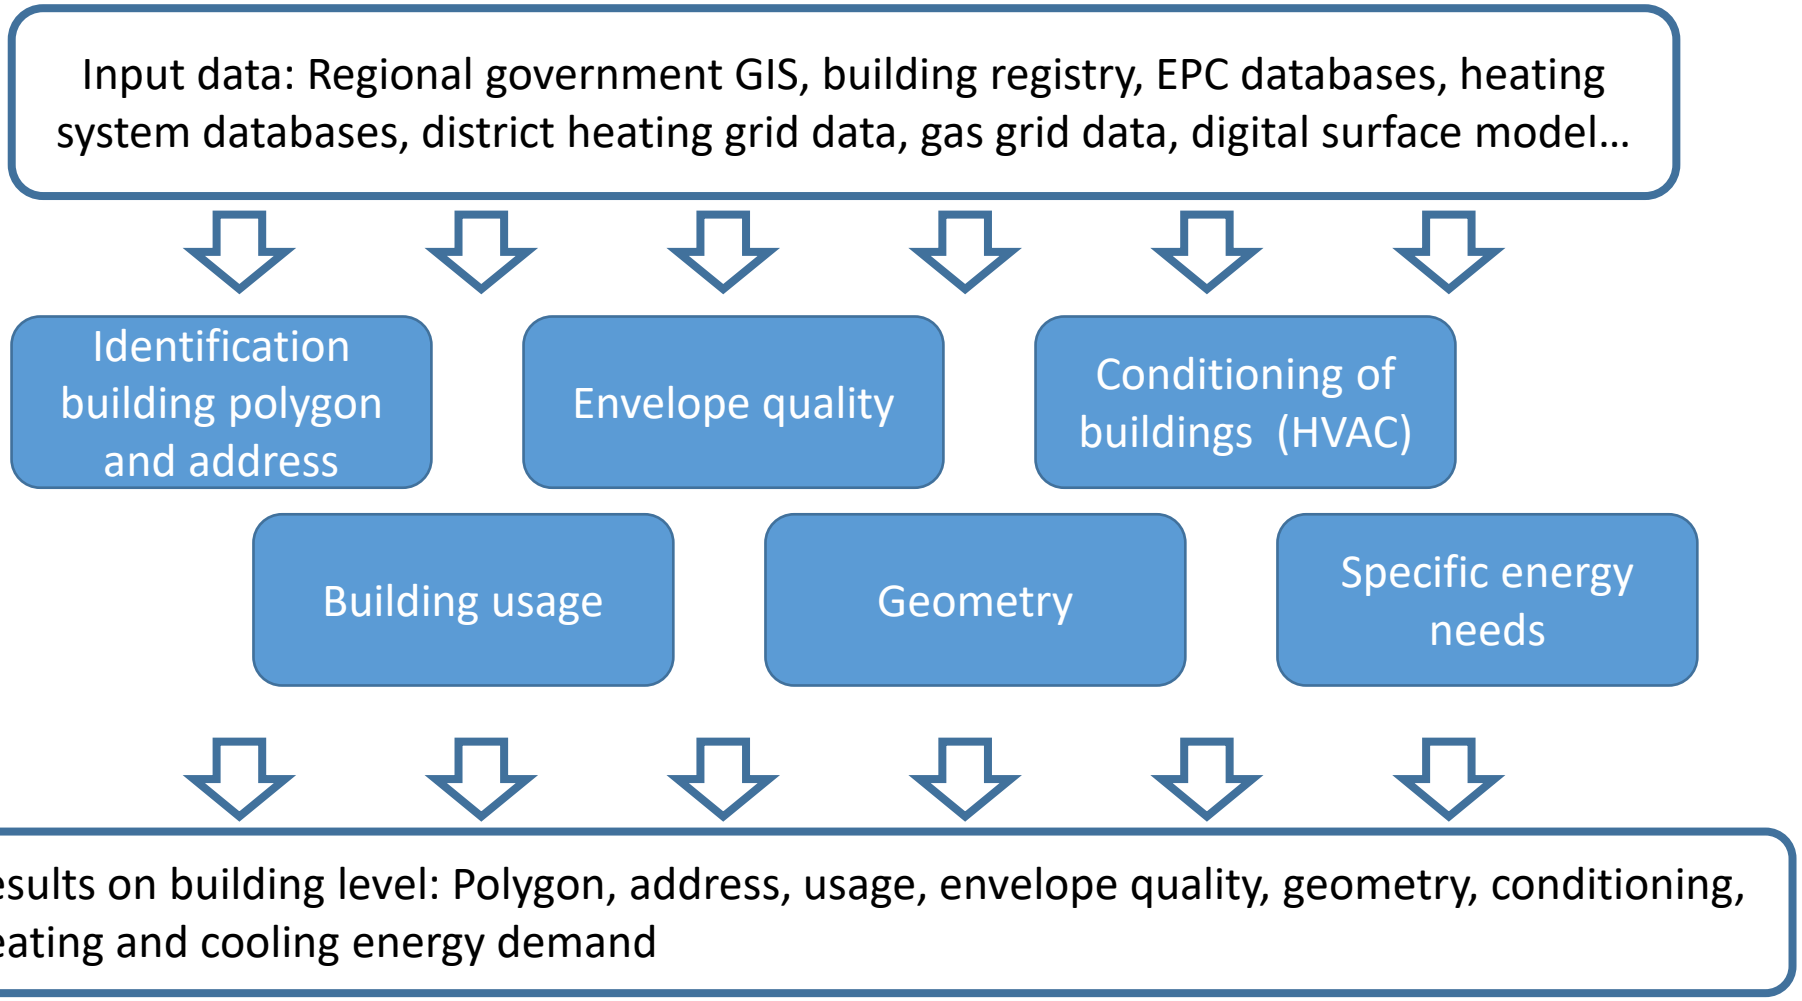
- For detailed planning of heating and cooling infrastructure, local, more specific data should be used

Heat mapping:

Top down approaches vs. high granularity heat maps

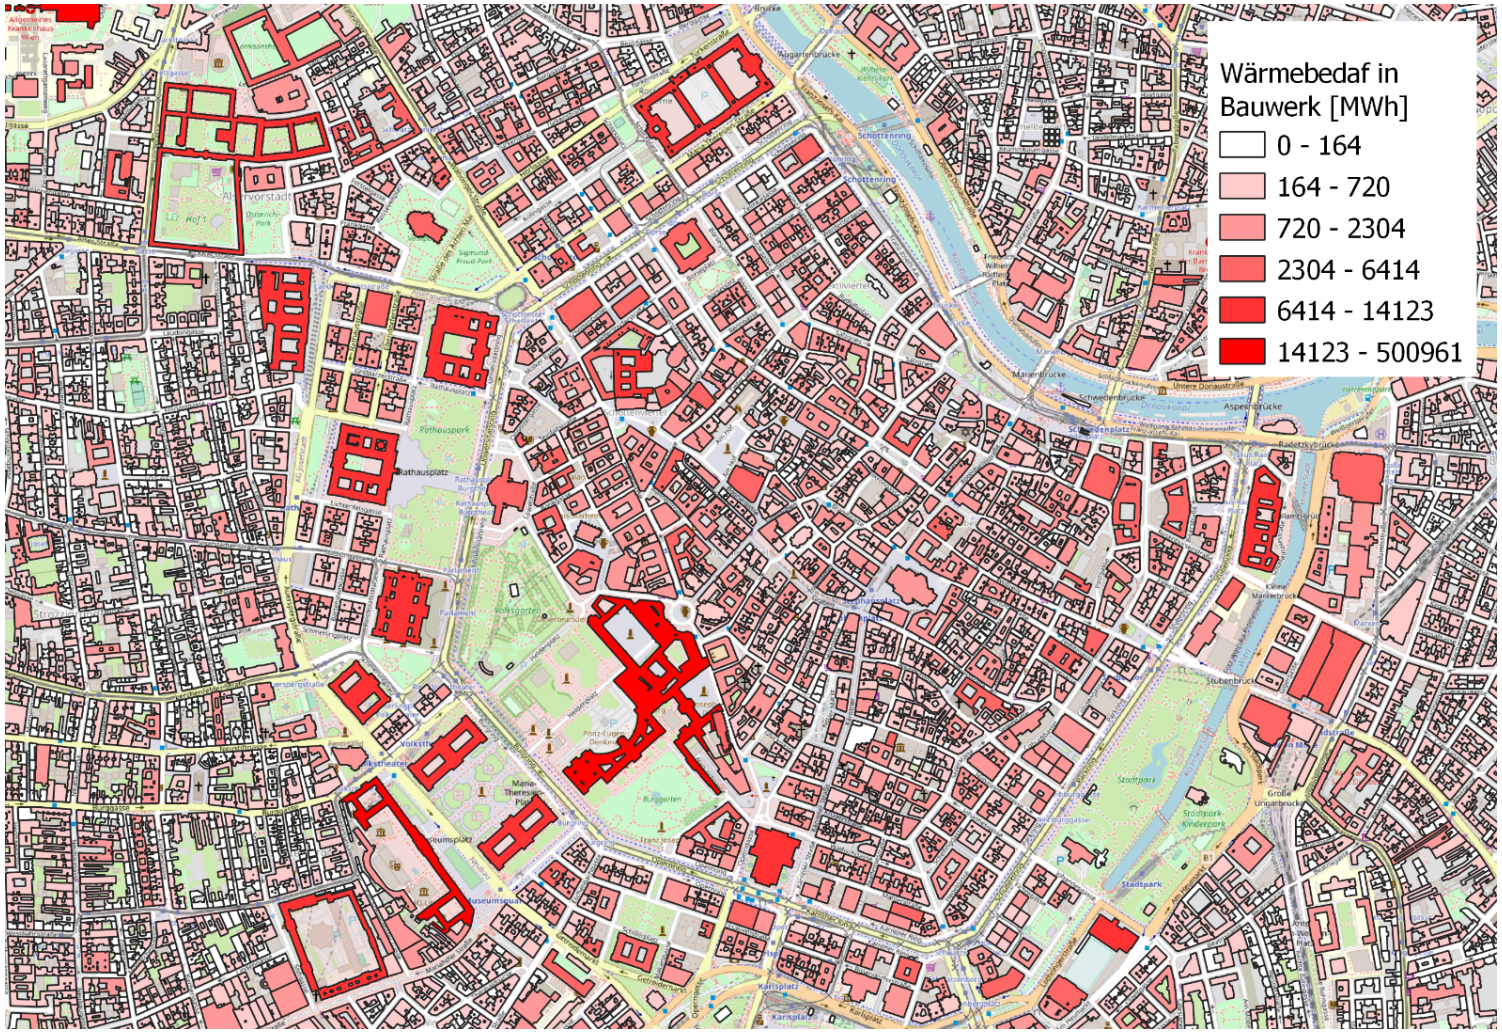


Overview of the process and the interaction of modules for determining building typology and heat demand maps on building level



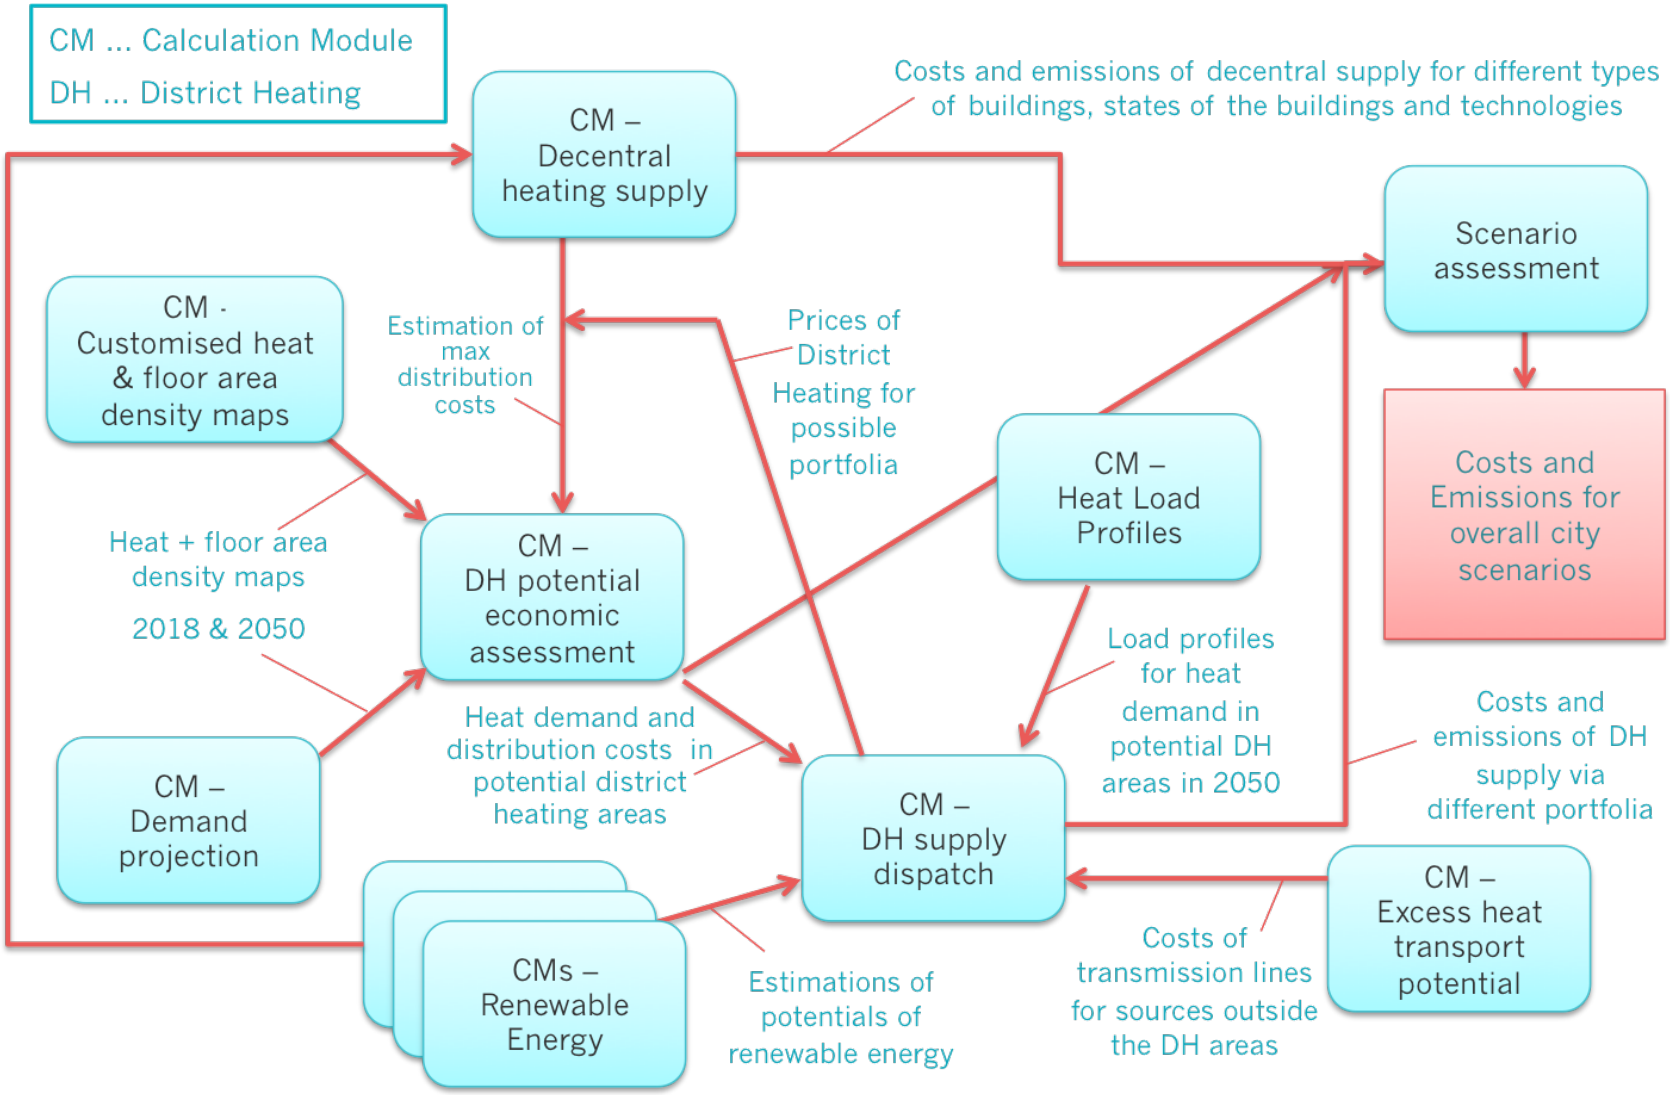
Source: Project Spatial Energy Planning (www.waermeplanung.at)

(Preliminary) results: heat demand map on building level to be regularly updated based on background data



Mapping is a means, not an end in itself

Hotmaps scenario toolchain



The case of Frankfurt: current and possible future heat maps

Heat demand density maps of Frankfurt for 2017 (top left),
2050 with 35% savings (top right),
2050 with 46% savings (bottom left) and
2050 with 53% savings (bottom right)

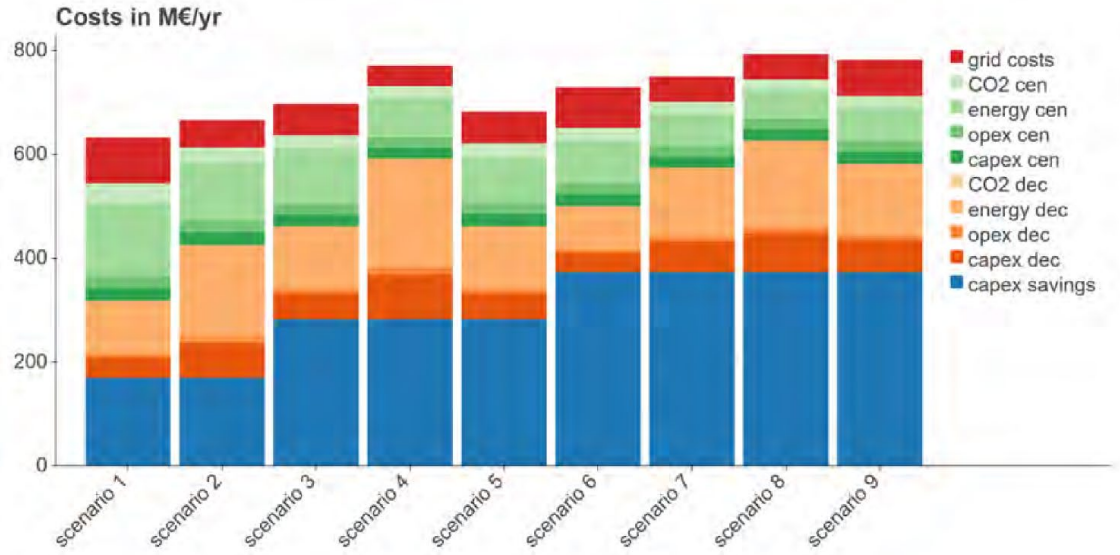
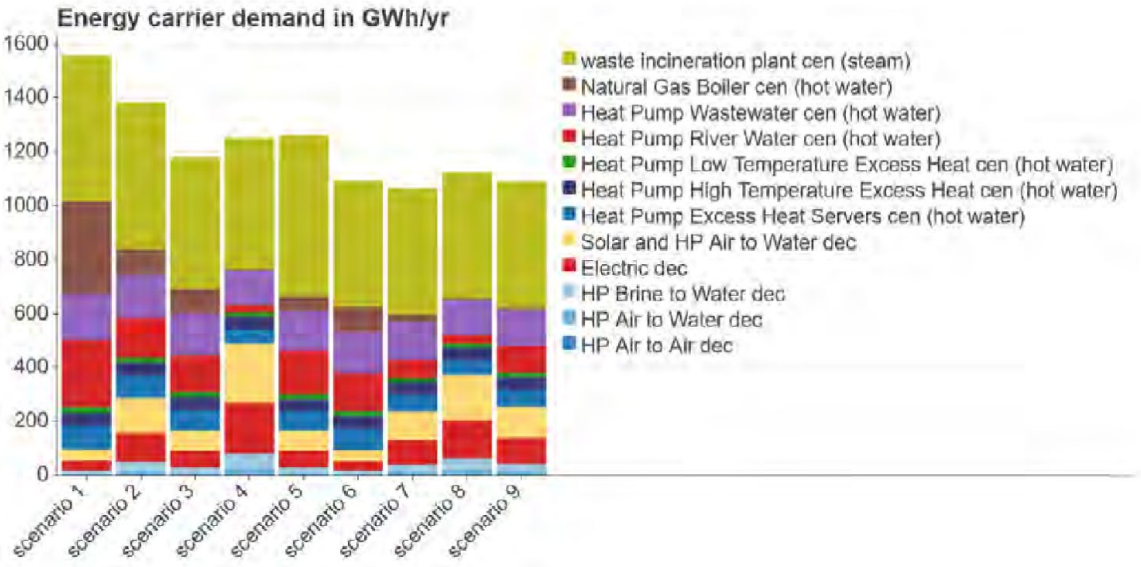
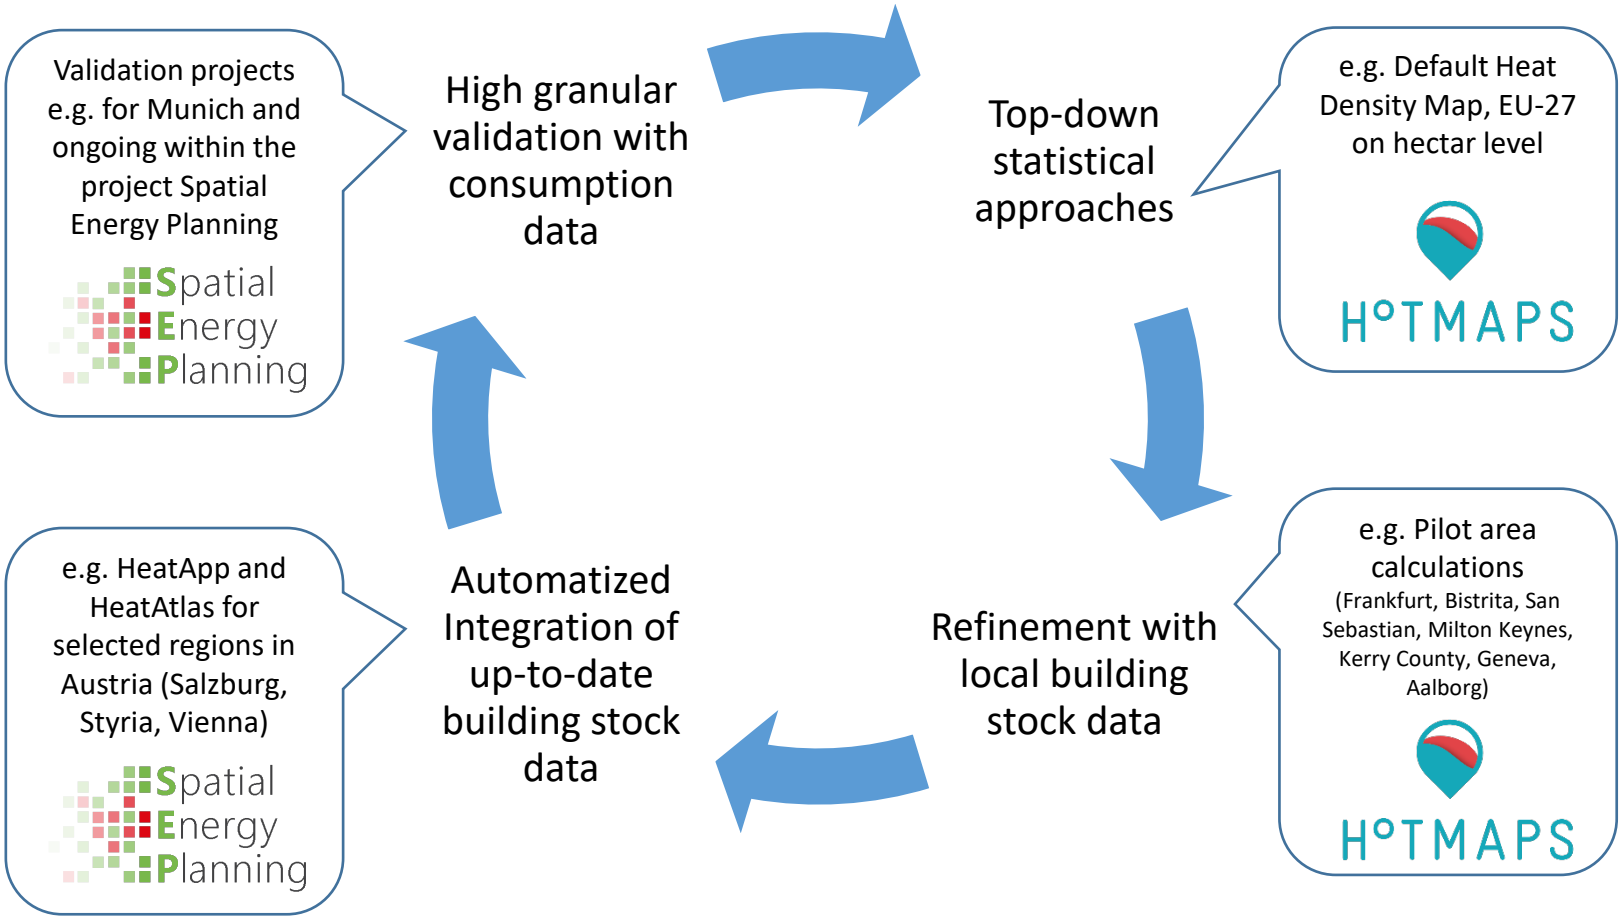
The case of Frankfurt: Comparing different possible scenarios of future heat supply and demand





Heat mapping:

Top down approaches vs. high granularity heat maps



Summary and conclusions

- Key uncertainties
  - Building height
  - Number of floors (for large non residential buildings)
  - Specific energy needs
    - Insulation of buildings
    - Usage and user behaviour
  - Information on HVAC system (Type, age, efficiency)

- Need for linking existing data sources (chimney sweepers, installers, different public authorities, EPC databases, building registries, heating system databases …)

- Trade-off between required resources to set-up a consistent building stock model and the related heat map on the one hand and the uncertainties related with available default heat density maps

- Suitable approach depends on available data (and available resources to improve them) and the concrete policy aim, questions and needs

Thank you!
